INTRODUCTION

Intestinal Parasitic Infections (IPI) are accountable for considerable morbidity in a vast majority of the population, particularly in developing countries. Pathological parasitic infections often lead to malnutrition, anaemia, cognitive impairment and increased susceptibility to other infections. Low socioeconomic status, poor hygiene, paucity of potable water, low literacy rates, large family size and poor health status of the host are significant risk factors contributing to these infections. Almost a quarter of the world’s population is infected with intestinal parasites causing morbidity, which almost certainly represents just the tip of the iceberg. Globally, 740 million people have been reported to be infected with hookworm and another 300 million with Enterobius vermicularis.

Parasitic co-infections are not a rarity, especially in populations with limited medical access. Numerous studies have established the dramatic effects of co-infections in susceptible populations, such as retro-positive patients. Furthermore, many cases with co-infections of multiple species of helminths have been reported in medical literature. However, hookworm-pinworm co-infection in an immunocompetent host has rarely if ever been reported. Parasitic co-infections cannot be overlooked and demand detailed investigations, since they may alter both treatment and susceptibility to infections. Here, we present a rare case of a hookworm-pinworm co-infection from a tertiary care teaching hospital in South India.

KEYWORDS

Dual Infection, Hookworm, Enterobius vermicularis.

ABSTRACT

Helminthic infections as a major cause for morbidity in the third world are not unknown. Because of limited medical access, co-infections of parasites in patients, especially from the lower socioeconomic strata is more often a norm than sporadic. Hookworm infections have frequently been reported along with other helminths and protozoans. Surprisingly, however, hookworm-pinworm co-infections have seldom if ever been reported. The implications of this dual infection in terms of intestinal microbial antagonism or synergy, prevalence, natural history of the disease and therapeutic options is therefore uncharted territory in the vast expanse of Intestinal Parasitic Infections (IPI). We discuss here a case of an immuno-competent adult male harbouring this unusual co-infection, questioning innumerable intestinal immune mechanisms that check such infections.

INTRODUCTION

Helminthic infections as a major cause for morbidity in the third world are not unknown. Because of limited medical access, co-infections of parasites in patients, especially from the lower socioeconomic strata is more often a norm than sporadic. Hookworm infections have frequently been reported along with other helminths and protozoans. Surprisingly, however, hookworm-pinworm co-infections have seldom if ever been reported. The implications of this dual infection in terms of intestinal microbial antagonism or synergy, prevalence, natural history of the disease and therapeutic options is therefore uncharted territory in the vast expanse of Intestinal Parasitic Infections (IPI). We discuss here a case of an immuno-competent adult male harbouring this unusual co-infection, questioning innumerable intestinal immune mechanisms that check such infections.
Parameshwarappa KD et al reported a rate of 19.9% for the same.12

Hookworm co-infections with other helminths and protozoans have been reported in the past. A combination of Ascaris lumbricoides and hookworm had the highest prevalence (2.96%) followed by hookworm and Taenia spp. (1.48%) in a recent study by Ragnanathan et al.11 Other researchers have reported similar results with their experience in dual parasitic infestations. However, a co-infection of hookworm with Enterobius vermicularis has not been published so far in medical literature to the best of our knowledge.

Seldom reported we have yet to decipher the implications of such co-infections in immunocompetent hosts, especially in the context of natural history of the disease and therapeutic options. Although albendazole or mebendazole have been the mainstay of therapy against hookworm since times long past, a study by Blackwell et al concluded that antiparasitic agents may provide short-term benefits, but do not appear to have lasting effects due to constant reinfection.15 An effective treatment for either parasite is not likely without a coalition of short-term therapy and long-term improvements in sanitation systems and access to clean drinking water besides health awareness amongst the masses.

**Fig. 1:** Egg of Hookworm (below) with Thin Hyaline Shell and Blastomeres (60 x 36 µm) and Planoconvex Egg of Enterobius Vermicularis (55 x 30 µm) (above) seen on Iodine Wet Mount Preparation (40X)

**CONCLUSION**

The focus of most parasitic co-infections has been centred mainly on immunologically challenged and paediatric populations. Little has been spoken about these infections in apparently immunocompetent adult hosts. Pathogenic mechanisms of the establishment of these infections in a hostile intestinal niche and their consequences are yet to be clearly elucidated. Co-infections with multiple parasites cannot be overlooked clinically or diagnostically. The need of the hour is also to target appropriate public health measures and awareness, to where they are yet to see the light of the day, viz. rural regions of the developing world.
