ABSTRACT

BACKGROUND

Domestic accidents are worldwide public health problems. The consequences of a domestic accident may prove disastrous, as it may result in disability and loss of productivity. In this context, the present study was carried out to characterize the occurrence of domestic accidents in the selected rural community.

AIMS

To study the prevalence of domestic accidents in the selected rural population and its association with various socio-epidemiological factors.

SETTINGS AND DESIGN

Community-based cross-sectional study.

MATERIALS AND METHODS

Complete information from 372 households consisting of 1497 individuals was collected through semi-structured questionnaire. A case was considered as domestic accident when any of these individuals had met with an accident inside the house or in the immediate surroundings of the house during the last 6 months from the date of survey. The collected data were tabulated and analysed using SPSS software version 21.

STATISTICAL ANALYSIS USED

Frequency, proportions and Chi-square test.

RESULTS

The prevalence of domestic accidents was found to be 4.6%. The most common accidents reported was falls (65%). Other accidents noted were burns, scalds, cuts and lacerations and accidental poisoning. Accidents were reported in significantly higher proportion in 50 and above age groups and in females. Higher proportion of accidents occurred during the morning and evening hours.

CONCLUSIONS

The present study was an attempt to highlight the epidemiological features of domestic accidents in the study area. It also tried to address issues in prevention of domestic accidents. Eg: Health Education in local language regarding prevention of accidents and to prevent accidental falls.

KEYWORDS

Domestic Accidents, Cross Sectional Study and Rural Population.

INTRODUCTION

Domestic accidents are worldwide public health problems. Accidents can take place in a wide variety of environments and there is a possibility of accidents in every sphere of human life: at home, at play and at work.(1)

The problem is more grave in developing countries, particularly in rural areas, shanty towns or informal dwellings.(2,3)

Every domestic accident brings a varying measure of distress to the victim as well as the family members. The consequences may be disastrous, both for the individual and the society when the accident results in permanent disability, as the victim loses his earning capacity and may not be able to enjoy a normal active life. Children in particular are more vulnerable to domestic accidents, resulting in disability and loss of future productivity.(4,5)

These accidents have not so far been recognized to the same extent as traffic and work-related injuries, largely because they have not been effectively counted.

Financial or Other, Competing Interest: None.

Since prevalence studies on domestic accidents in rural area were not widely available particularly in rural Tamilnadu, we have preceded this study to find out the prevalence of domestic accidents and their association with various socio-demographic factors, so that the public health planners can identify potential socio-environmental factors to reduce these accidents in the selected rural area.

METHODOLOGY

The present cross sectional study was conducted in three randomly selected villages namely Perusathanam, Elampillai and Magudachavadi which is the rural field practice area of Annapoorna Medical College and Hospital, Salem District, Tamilnadu from December 2014 to February 2015. There were 10 villages served under the field practice area of Annapoorna Medical College. There were total of 450 households in these three villages. A household included all the persons who occupy a housing unit or a dwelling unit.

With reference to the study, conducted in South India, the prevalence of domestic accidents was taken as 9.6% and the sample size arrived at 1128 with 20% allowable error with 20% non-response rates. We have covered the sample size of 1497 in 372 households in the selected three villages during the study duration. Written consent was taken from the head of the family/adult person whom we have interviewed after explaining the objectives and procedure of the study.

A semi-structured questionnaire was used to collect the data on the background information, type and time of accident, morbidity due to that in the last six months among 372 households by interviewing the available eldest adult belonging to the particular household. Approval from the Institutional Ethics Committee was taken prior to the study initiation.

Domestic accident was considered when any of these individuals had met with an accident inside the house or in the immediate surroundings of the house during the last 6 months from the date of survey. Overcrowding was considered when number of persons per room exceeded the accepted standards.[7,8]

The collected data were tabulated and analysed in terms of frequencies and proportions. To study the relationship between the various socio-demographic factors with domestic accidents, Chi-square test was applied. P-value less than 0.05 was considered significant.

RESULTS

Socio-demographic Characteristics of the Study Population

This present study was done among 372 households comprising 1497 population, among which males and females comprise 780 (52%) and 717 (48%) respectively. Majority of the respondents were illiterates 411 (27.5%). The main occupation of the surveyed villages were agriculture and weaving. The annual income for majority of the families were >Rs. 1 lakh 188 (32.7%) and >Rs. 64908 (20.5%). Around 52% (192) of the respondents were living in semi-pucca houses.

Determinants Influencing Domestic Accidents

Prevalence of domestic accidents among the surveyed population found to be 4.6% (69). Majority of the domestic accidents include falls 45 (65%) and cut injury from sharps 18 (26.1%), cuts and burns 12 (17.4%) (Table 2).

The most common age in which the accidents encountered were 50 and above was 20 (29%), followed by 31-40 years was 12 (17%) (Table 3). The reported accidents were more common among females 41 (59%) and it is found to be statistically not significant p>0.05 (Table 3). Regarding occupation reported accidents was high among the unskilled workers, which was found to be statistically significant (p<0.0002) (Table 3). The place of occurrence of accidents were mainly space around home 39 (56%) and bathroom 19 (28%) (Table 4). Majority of the incidents took place in the morning 29 (42%) than evening 23 (33%) (Table 4).

DISCUSSION

A study done by Ramesh Masthi et al[6] found that the prevalence of domestic accidents in the rural community was found to be 9.6% and more among females compared with males. Similar findings has also been noted in the present study that the prevalence was 4.6% (In 372 households) and females encountered many number of accidents 41 (59%) than males 28 (41%), which was found to be statistically not significant (p>0.05). Similar observations has been noted in various studies done by Dinesh J Bhanderi,[9] Vani Madhavi Kommula,[10] and Devroye et al.[11] Chaurasia and Shukul also reported a higher incidence of domestic accidents in females in their study.[12] Neghab et al. also reported similar gender difference in their study.[13]

The most common accident reported in the present study was falls, i.e. 65.0%. This category included fall on floor, slipping in bathroom and fall from stairs. Other accidents noted were burns, electrocution, injuries from sharps and accidental poisoning. Similar observations has also been noted by Dinesh J Bhanderi,[9], falls were around 71.0% in the rural Karnataka. Many other studies carried out in India and abroad also report falls as the commonest mode of injury.[4,5,14,15] In contrast to this a study done by Vani Madhavi Kommula,[10] reported that most common accidents reported were injuries from sharp or pointed instruments (32.2%) followed by falls (26.9%). Chaurasia and Shukul,[12] observed a higher proportion of burns and scalds in their study. Neghab et al.[13] reported that burns and sharp-object injuries were the most common types of domestic accidents. In accidental poisoning group, one case of cleansing acid consumption was reported. Contrast to this Vani Madhavi Kommula,[10] noted that 5 children with kerosene poisoning and 2 with shampoo poisoning.

Analysing further the occurrence of accidents among the individuals in the age group of 50 and above it was found to be marginally higher, though not significant compared to other age groups[Table 3].

Considering the time of accident, 29 (42%) accidents occurred during the morning hours, 23 (33%) in the evening and 3 (5%) during the night. So, a higher proportion of accidents occurred during the morning and evening hours (Table 4). As far as treatment-seeking pattern is concerned, majority of the respondents prefer Govt. and Private Hospitals 42 (61%) followed by hospitals alone 22 (32%) (Table 5). No death related to domestic accident was reported in the present study. Though Neghab et al. reported mortality rate due to domestic accidents was quite high, i.e. 1.3% in their study.[13]
CONCLUSION
The present study was an attempt to highlight the epidemiological features of domestic accidents in the study area. It also tried to address issues in prevention of domestic accidents. Eg. Health Education in local language regarding prevention of accidents and to prevent accidental falls. Thus, domestic accident cases are a special group in themselves reflecting more clearly than any other, the character and way of living of people. A broader study involving the whole rural population may provide a clearer picture of the epidemiology of domestic accidents in our country.

Limitations
The results of the study cannot be generalised since the sampling was a convenient sampling. All the victims who have met with domestic accidents could not be interviewed personally since some of them were not available during the interview. Some degree of recall bias, especially with reference to trivial injuries could not be ruled out.

Recommendations
We are beginning to realize that domestic accidents is a public health problem of great magnitude of all ages. The prevention of domestic accidents can be attempted locally through the individual and the family by creating awareness about the occurrence of accidents and the ways to prevent them.
