ABSTRACT

BACKGROUND

Preoperative difficulty estimation helps deciding whether to proceed with a minimally invasive approach, perform an open procedure or make a referral to a more experienced surgeon. Laparoscopic cholecystectomy outcome is particularly affected by the presence and severity of inflammation, age, male sex, etc.

To determine the preoperative predictive factors for difficult laparoscopic cholecystectomy.

MATERIAL AND METHODS

A total of 100 patients were enrolled to this study. Clinical examination, laboratory data and ultrasound study was performed for all patients.

CONCLUSION

Preoperative prediction of risk factors of difficult laparoscopic cholecystectomy is an important point for operative planning and the high risk patients may be informed accordingly.

KEYWORDS

Predictor’s, Difficult Laparoscopic Cholecystectomy.

INTRODUCTION

Laparoscopic Cholecystectomy (LC) has become the gold standard in the treatment of symptomatic gallstones.1 LC has replaced open cholecystectomy as the therapeutic modality in the treatment of Cholelithiasis.1 Decreased postoperative pain, earlier oral intake, shorter hospital stay, early resumption of normal activity and improved cosmesis have been well recognised after LC.2 A significant reduction in the incidence of wound complications and postoperative ileus has been documented in patients undergoing LC.3 It is important to realise that the need for conversion to laparotomy is neither a failure nor a complication, but an attempt to avoid complication and ensure patient safety.4 Prediction of a difficult Laparoscopic cholecystectomy would allow the surgeon to discuss the likelihood of conversion with the patient and prepare him/her psychologically.4,5 Another benefit would be to allow more efficient scheduling of the operating lists and ensuring the availability of a well experienced laparoscopic surgeon for the procedure.4 Our study is based on the assumption that difficult laparoscopic cholecystectomy can be predicted and our study has been designed to identify the associated preoperative predictors.

METHODOLOGY

This was a prospective study conducted in Department of Surgery, Dr. Susheela Tiwari, Government Medical College and Associated Government Hospital, Rampur Road, Haldwani, Dist., Nainital, Uttarakhand, from Nov. 2013 to Sept. 2015. The patients who underwent laparoscopic cholecystectomy were included in this study. Total number of patients is 100 and includes both admitted either as routine or emergency cases.

The Following were the Exclusion Criteria

Exclusion Criteria

• The patients who were taken for open cholecystectomy directly.
• Severe restrictive pulmonary disease (These patients cannot tolerate CO₂ pneumoperitoneum).
• Suspected gall bladder malignancy.
• Patients unfit for general anaesthesia.
• Patients not giving informed written consent.

The selected patients were then told about the procedure and written informed consent was taken. Patients were also informed about the possibility of conversion to open cholecystectomy. In this study, we have taken preoperative predictors of difficult laparoscopic cholecystectomy. Preoperative predictors were further divided into clinical, biochemical and ultrasonographic predictors.

PREOPERATIVE FACTORS

Clinical Factors

1. Age.
2. Sex.
3. Duration of pain.
4. Recurrent biliary colic.
5. History of jaundice.
7. Previous history of upper abdominal surgery.
8. Gall bladder lump.
9. H/O comorbid conditions like diabetes, hypertension.

**Biochemical Factors**
1. Direct bilirubin > 0.4 mg/dL (normal lab range 0.1 – 0.4 mg/dL).
3. Total Leukocyte Count > 11000 /cumm (normal lab range 4000-11000/cumm).

**Ultrasonographic Factors**
1. Gall bladder wall thickening > 4 mm/Oedema of Gall bladder wall.
2. Pericholecystic fluid.
3. Contracted Gall bladder.
4. Single/multiple gall stones/location of stones (neck, fundus of gall bladder).
5. Common bile duct diameter/evaluation of cystic duct.
7. Existing comorbid conditions detected on ultrasonography like pancreatitis, cholangitis.
9. Liver cirrhosis.

**OBSERVATIONS AND RESULT**
The findings of pre-operative clinical, biochemical and ultrasonographic factors of all patients were correlated with total duration of surgery and intraoperative difficulties encountered during laparoscopic cholecystectomy to find out the predictors of difficult laparoscopic cholecystectomy.

Table 1: Age Distribution

Out of 100 patients, 21 (21%) were Males and 79 (79%) were Females.

Most frequent clinical presentation was recurrent colic (80 cases), H/O jaundice was present in 5 cases, whereas h/o biliary pancreatitis was present in 6 cases; 3 patients presented with h/o pain for less than 3 days. GB lump was palpable in 8 cases; 2 patients had h/o upper abdominal surgery in past.

Table 2: Distribution of Clinical Factors

Most frequent biochemical factors were:
- Direct bilirubin > 0.4 mg% in 11 patients (11%)
- ALP >306 IU/L in 24 patients (24%)
- TLC >11000 in 4 patients (4%)

Table 3: Distribution of Biochemical Factors

- Analysis of biochemical factors in patients undergoing laparoscopic cholecystectomy showed that Direct bilirubin >0.4 mg% was seen in 11 (11%) cases.
- In 24 (24%) patients, Alkaline Phosphatase was >306 IU/L.
- 4 (4%) patients had TLC >11,000.
Ultrasonographic Factors | Total No. of Patients | Percentage %
--- | --- | ---
Single calculus | 20 | 20%
Multiple calculus | 80 | 80%
CBD dilated (≥ 6 mm) | 17 | 17%
CBD stone | 4 | 4%
GB wall thickness >4 mm | 22 | 22%
Pericholecystic fluid | 4 | 4%
Contracted GB | 7 | 7%
Distended GB | 47 | 47%
Liver cirrhosis | 4 | 4%
Mucocele GB | 12 | 12%
Empyema GB | 2 | 2%
Gangrenous GB | 1 | 1%

**Table 4: Distribution of Ultrasonographic Factors**

- Analysis of ultrasonographic factors showed that most frequent finding was multiple calculi 80 (80%) cases.
- Next most common finding on ultrasonography was distended GB 47 (47%) cases.
- Patients with Gallbladder wall thickness > 4 mm were 22 cases (22%).

Table 5: Distribution of Total Duration of Surgery

</table>

The above table shows that most frequent finding was multiple calculi 80 (80%) cases.
- Next most common finding on ultrasonography was distended GB 47 (47%) cases.
- Patients with Gallbladder wall thickness > 4 mm were 22 cases (22%).
- Patients with Pericholecystic fluid 4 (4%) cases, Contracted gallbladder 7 (7%) cases and Liver cirrhosis 4 (4%) cases.

- Analysis of ultrasonographic factors showed that most frequent finding was multiple calculi 80 (80%) cases.
- Next most common finding on ultrasonography was distended GB 47 (47%) cases.
- Patients with Gallbladder wall thickness > 4 mm were 22 cases (22%).
- Patients with Pericholecystic fluid 4 (4%) cases, Contracted gallbladder 7 (7%) cases and Liver cirrhosis 4 (4%) cases.
Laparoscopic cholecystectomy was difficult in 21 cases (25.90%) with recurrent colic, 12 cases (15.19%) of laparoscopic cholecystectomy was difficult in female patients; whereas in male patients in 61.90% of cases laparoscopic cholecystectomy was difficult.

**Table 7:** Difficulty Assessment in Relation to Biochemical Factors

<table>
<thead>

</tbody>
</table>

Out of 11 cases with direct bilirubin > 0.4 mg% 8 cases (72.70%) of laparoscopic cholecystectomy was difficult; in 24 patients Alkaline Phosphatase was > 306 IU/L, in them 10 cases (41.70%) of laparoscopic cholecystectomy were difficult; 4 patients had TLC > 11000 and in all of them laparoscopic cholecystectomy was difficult.

**Fig. 7:** Difficult Assessment in Relation to Biochemical Factors

Out of 80 cases with multiple calculi on ultrasonography, 22 cases (27.5%) of laparoscopic cholecystectomy was difficult, 15 (31.9%) cases with distended GB out of 47 cases of laparoscopic cholecystectomy were difficult.

- In patients with gallbladder wall thickness > 4 mm (22 cases), 77.3% (17 cases) of laparoscopic cholecystectomy were difficult.
- In patients with Pericholecystic fluid (4 cases), contracted gallbladder (7 cases) and Liver cirrhosis (4 cases), all laparoscopic cholecystectomies were difficult.

**Fig. 8:** Difficult Assessment in Relation to Ultrasonographic Factors
DICUSSION

This study was done to find out the predictors of difficult laparoscopic cholecystectomy by analysis of pre-operative clinical, biochemical and ultrasonographic factors. The statistically significant factors in our study, which can predict difficult laparoscopic cholecystectomy were:

a. Gallbladder wall thickness > 4 mm (n=22; p value=0.001)
b. Pain < 3 days (n=3; p value=0.000)
c. Dilated CBD (n=17; p value=0.011)
d. Distended GB (n=47; p value=0.018)
e. Male gender (n=21; p value=0.003)
f. History of previous upper abdominal surgery (n=2; p value=0.003) 
g. Direct bilirubin > 0.4 mg% (n=11; p value=0.001)
h. Multiple stones in GB (n=80; p value=0.002)

Gallbladder Wall Thickness

In our study gallbladder wall thickness > 4 mm was seen in 22 patients, out of which 18 laparoscopic cholecystecotomies were difficult. So, it is statistically highly significant predictor for difficult laparoscopic cholecystectomy (p value=0.001). Fried et al reported that thickened gallbladder wall was significant predictor of conversion of Laparoscopic to open cholecystectomy.(6)

Acute Cholecystitis

According to Rattner DW et al, the changes that occur with acute cholecystitis are oedema, hypervascularity, venous engorgement and gallbladder distention. Within 72 hours of symptoms the tissue planes are oedematous and inflamed but are easier to dissect, having no adhesions at all. But after 72 hours, the tissue becomes more friable and becomes dangerous and risky to dissect.(7)

In our study also 4 patients presented with acute cholecystitis and in all of them laparoscopic cholecystectomy was difficult. This may be because all of them presented after 72 hours of onset of symptoms; 2 patients had empyema of gallbladder, but both of them were completed successfully with laparoscopic cholecystectomy.

Male Gender

In our study out of 21 male patients, 11 had difficult laparoscopic cholecystectomy. It is statistically significant predictor for difficult laparoscopic cholecystectomy (p value=0.003).

Nachnani J in his study also reported that male gender was a significant predictor for difficult laparoscopic cholecystectomy.(8)

Fried et al reported that male gender was a significant predictor of conversion of Laparoscopic cholecystectomy to open cholecystectomy.(6)

Previous Upper Abdominal Surgery

In our study, h/o previous upper abdominal surgery was present in 2 cases and both turned out to be difficult. It is statistically significant predictor for difficult laparoscopic cholecystectomy (p value= 0.003).

The published prospective study by Nachnani J reported that past history of upper abdominal surgery is a significant clinical predictor of difficult laparoscopic cholecystectomy.(6)

Direct Bilirubin > 0.4 mg%

In our study, we observed that Direct bilirubin > 0.4 mg% is statistically significant factor for prediction of difficult laparoscopic cholecystectomy. Direct bilirubin was raised in 11 patients, out of which laparoscopic cholecystectomy turned out to be difficult in 8 patients (p value=0.001). Del Pin CA et al published a study of the relationship of pathology and operative time and outcome of laparoscopic cholecystectomy in both acute and chronic cholecystitis cases, which concluded that abnormal liver function tests are associated with longer operative time.(9)

Multiple Gallbladder Calculi

In our study also multiple GB calculi (p value=0.002) is statistically significant predictor for difficult laparoscopic cholecystectomy. Among 80 patients who were having multiple calculi, 22 cases turned out to be difficult.

According to Y. K. S. Vishwanath, retrieval of gall bladder through the port site opening is technically difficult and challenging when it is packed with multiple calculi.(10)

Distended Gallbladder

In our study among 47 patients who were having distended gall bladder, 15 cases turned out to be difficult which is statistically significant (p value=0.018).
Age > 60 Years

In our study, total number of patients with age > 60 years were 14 and 7 cases turned out to be difficult. Although, it is statistically insignificant (p value=0.67) factor for predicting difficult laparoscopic cholecystectomy, but we encountered problems during dissection in Calot’s triangle in 6 patients and omental and duodenal adhesions to gallbladder was present in 4 patients. Gallbladder wall was also thickened in 4 cases.

Ammori B J et al reported age older than 55 years as a predictor of extended operation time (more than 90 minutes).

Fried et al reported that increasing age was a significant predictor of conversion of laparoscopic cholecystectomy to open cholecystectomy. (6)

H/O Jaundice

In our study, h/o jaundice is an insignificant (p value=0.71) predictor for difficult laparoscopic cholecystectomy. The study by Del Pin CA et al concluded that abnormal liver function tests are associated with longer operative time. (6)

Recurrent Biliary Colic

Recurrent biliary colic (n=80; p value=0.79) is statistically insignificant factors in our study.

Gallstone (Biliary) Pancreatitis

In our study, h/o gallstone pancreatitis was present in 6 cases only 2 surgeries were difficult amongst them. It is statistically insignificant factor to predict difficult laparoscopic cholecystectomy (p value=0.42).

According to Nadnani J et al, history of biliary pancreatitis is a significant predictor for difficult laparoscopic cholecystectomy. (8)

Serum Alkaline Phosphatase > 306 IU/L

In our study, we observed that serum alkaline phosphatase > 306 IU/L was present in 24 cases and only 10 cases were difficult. It is statistically insignificant factor for prediction of difficult laparoscopic cholecystectomy (p value=0.53).

Rattner et al concluded that raised serum alkaline phosphatase was associated with severe inflammation and failure of laparoscopic cholecystectomy. The significant parameter identified was elevated alkaline phosphatase level. (7)

TLC > 11,000 cu/mm

In our study we observed that TLC > 11,000 cu/mm was present in 4 cases and all of them turned out to be difficult; yet it is statistically insignificant factor for prediction of difficult laparoscopic cholecystectomy (p value=0.37).

A study conducted by Rattner et al to determine the preoperative factors that correlate with successful completion of a laparoscopic cholecystectomy in patients with acute cholecystitis, which showed that the clinical parameters with severe inflammation were significantly associated with failure of laparoscopic procedure. The significant parameter identified was leucocytosis. (7)

Pericholecystic Fluid

In our study, pericholecystic fluid on sonography was seen in 4 patients and in all of them laparoscopic cholecystectomy was difficult; yet it is statistically insignificant factor in predicting difficult laparoscopic cholecystectomy (p value=0.34).

Hans–Peter Dinkel et al reported that on sonography pericholecystic fluid is a most specific indicator of technical difficulties during laparoscopic cholecystectomy. (12)

Contracted Gallbladder

In our study, we observed that laparoscopic cholecystectomy was difficult in all 7 patients with contracted gallbladder. Though statistically insignificant may be because of small number of cases, contracted gallbladder with thick-walled gallbladder is a strong predictor of difficult laparoscopic cholecystectomy (p value 0.001).

Lal P et al reported that contracted gallbladder on ultrasonography was a predictor of difficult laparoscopic cholecystectomy. (13)

Liver Cirrhosis

In our study liver cirrhosis was present in 4 cases and all of them were difficult laparoscopic cholecystectomies, yet it is statistically insignificant (p value=0.62) factor for predicting difficult laparoscopic cholecystectomy.

Zakro et al published a study of 24 liver cirrhotic patients who underwent laparoscopic cholecystectomy. The index of conversion was 4.16% (1/24) and mortality rate 0. The mean length of hospital stay was 2.9 days. The study concluded that use of laparoscopic cholecystectomy for gallstone disease is proposed in patients with liver cirrhosis as the first choice operative method for treatment. (14)

Dilated Common Bile Duct and Common Bile Duct Stones

In our study, dilated common bile duct > 6 mm is statistically significant predictor for difficult laparoscopic cholecystectomy (p value=0.11). Common bile duct was dilated in 17 patients, out of which 11 cases turned out to be difficult. Presence of common bile duct stones is statistically insignificant predictor of laparoscopic cholecystectomy (n=4, p value=0.76). Jansen S concluded that common bile duct diameter wider than 6 mm was found to increase significantly the risk of conversion of laparoscopic to open cholecystectomy. (15)

CONCLUSION

From the study we conclude that clinical, biochemical and ultrasonographic parameters collectively can help to predict difficult laparoscopic cholecystectomy in majority of the cases. These predictors can help the surgeon to get an idea of potential difficulty that he can face in that particular patient. On the basis of predictors, one can plan whether surgical laparoscopic trainee should do a particular case in learning phase or not.

On the basis of these predictors we can also know the approximate total time taken for surgery, so that operation theatre timings can be better planned in major institutions where time factor is very important. The best way to avoid complication is to anticipate it beforehand and take precautions accordingly. This will help the surgeon to select patients for laparoscopic cholecystectomy.
