ABSTRACT: Adenoid cystic carcinoma of the breast is a rare histopathological entity accounting for <1% of all breast cancers. Though morphologically similar to salivary gland neoplasms it carries a much better prognosis with a reported 10 year survival to be 90-100%. Surgery forms the mainstay of treatment with both simple mastectomy and breast conservation surgery being performed followed by adjuvant systemic and radiotherapy. Awareness of this rare variant of breast carcinoma is required for optimal treatment planning and to avoid any diagnostic dilemmas.

KEYWORDS: Adenoid Cystic Carcinoma of Breast, Basaloid Carcinoma, Breast Cancer, Cylindroma, Triple Negative Breast Cancer.

INTRODUCTION: Adenoid cystic carcinoma (Basaloid carcinoma, Cylindroma) though frequently associated with salivary glands can also occur at other sites of the body with a exocrine secretory glandular function like the maxillary sinus, tracheobronchial tree, nasopharynx, breast, prostate, lungs and the uterine cervix.⁶⁷ Adenoid cystic carcinoma (ACC) of breast is a rare entity accounting for 0.1-1% of all breast cancers.⁸¹⁰ Though morphologically ACC is similar to ACC of the salivary glands but it carries a much better prognosis with an excellent 10 year survival.⁸ Management is similar to invasive breast cancer and consists of mastectomy, axillary clearance, breast conservation, chemotherapy and radiotherapy. Here we are reporting a 55 year old woman with a tumor of right breast which proved to be this rare breast neoplasia.

CASE SUMMARY: A 55 year old postmenopausal woman presented with a history of lump in right breast for the 4 years. Clinical examination revealed a well circumscribed 2cm nodule in the upper outer quadrant of the right breast in close proximity to the nipple. The overlying skin was normal and there was no palpable axillary lymphadenopathy. Sonomammography revealed a 2.5×2×1.9cm solid focal lesion in right breast subareolar region. No architectural distortion or micro calcification was seen. Skin and subcutaneous tissue appeared normal. It was graded as BIRADS 4 [Figure 1]. Fine needle aspiration cytology was suggestive of salivary gland tumor likely adenoid cystic carcinoma. She was treated with wide excision of the lump. Histopathologic examination showed a grayish white 2×1×1.5cm lesion comprising of infiltrating tubules and cribriform like nests of basaloid epithelial cells showing monomorphic round nuclei and occasional small nucleoli.

Histopathologic examination showed a grayish white 2×1×1.5cm lesion comprising of infiltrating tubules and cribriform like nests of basaloid epithelial cells showing monomorphic round nuclei and occasional small nucleoli. These cell nests were punctuated by cystic spaces and cells arranged haphazardly around spaces [Figure 2].

DISCUSSION: Adenoid cystic carcinoma of breast commonly presents in an adult perimenopausal female as a breast lump which may or may not be painful. The associated pain has been reported to be due to contractile myoepithelial elements of these tumors and not due to perineural invasion which is uncommon in these tumors.⁴⁵ It is usually unilateral.⁶ This rare histopathologic entity of the breast is characterized by slow progression and good prognosis. A 90-100% 10-year survival rate is reported, and metastases to lymph-node and visceral organs is rare.⁷⁸

There is a paucity of literature on ACC breast due to the rarity of this disease with most studies being either case reports or cohorts. Geschickter first described adenoid cystic carcinoma of the breast. Galloway et al (1966) at Mayo clinic reported nine cases of adenoid cystic carcinoma occurring in the breast.¹ ACC mostly present as a unilateral breast lump which might be painful. There is a predilection for the periareolar region though all quadrants can be affected.³⁵ In our case it was a painless lump located in the upper outer periareolar region of the right breast. ACC has been reported to be found in conjunction with ipsilateral⁷ and contralateral breast cancer. An association with microglandular adenosis has also been reported.⁸ with certain authors suggesting that ACC arises in the background of microglandular adenosis.

The various growth patterns found in ACC breast are similar to those found in salivary glands: the classic cribriform pattern, as well as the solid, trabecular and glandular patterns. 14% of cases may show sebaceous differentiation and foci of adenosquamous differentiation may also be encountered.³⁴
The finding of a biphasic pattern of true lamina and pseudolamina and a biphasic cellular pattern of myoepithelial and epithelial cells is diagnostic of ACC. ACC breast shows triple negative phenotype i.e. lack of expression of ER, PR and HER2.[3,10] In our case the histology showed a cribriform growth pattern and immunohistochemistry showed a triple negative phenotype.

The prognosis of ACC is related to the histological grade. According to the grading given by Ro et al.[11] ACC are graded according to the proportion of solid growth - cases with either cribriform or glandular pattern are considered low grade/ G1 tumours, cases with <30% of solid elements are labelled as G2, whereas cases showing >30% of solid growth are classified as high grade/G3 tumours. With the increase in the percentage of solid elements, the risk of tumor development and postoperative recurrence also rises.[3,11,12]

Surgery remains the mainstay of treatment with both BCS and mastectomy described in literature. Simple mastectomy is the preferred treatment modality used by most surgeons due to the rarity of lymph node involvement by this tumor; its lower morbidity; and faster recovery.

REFERENCES:

However adjuvant systemic or radiation therapy is usually recommended due to the high recurrence rates of simple mastectomy.[12] The proposed treatment according to the pathological grading suggested by Ro et al.[11] is simple lumpectomy for grade 1 tumors, simple mastectomy for grade 2 tumors and mastectomy with axillary clearance for grade 3 tumors.

Due to the rarity of this disease the optimal treatment is yet to be determined. There are a few studies on hormone therapy, adjuvant chemotherapy and bio-immunotherapy and prospective trials are needed to determine the optimal treatment.

CONCLUSION: Adenoid cystic carcinoma of breast is rare and forms a diagnostic and therapeutic challenge for the clinician with a lack of consensus regarding the optimal treatment. More studies and prospective trials are required to further characterize the lesion and arrive at a consensus for treatment.
