ABSTRACT

BACKGROUND

Surgical site infections are the infections that occur within thirty days after the operative procedure (Except in case of added implants). Surgical site infections are the 3rd most commonly reported nosocomial infections accounting for a quarter of all such infections. A wide range of organisms are known to infect wounds like gram positive cocci, gram negative bacilli, spore formers, aerobes and anaerobes. Despite the advances in operative technique and better understanding of the pathogenesis of wound infections and wound healing, surgical site infections still remain a major source of morbidity and mortality. Hence, this study was done to identify the aetiological bacterial agents and their antibiogram pattern and the risk factors associated with surgical site infections.

METHODS

Wounds were examined for signs and symptoms of infection in postoperative ward. All the pus swabs were processed and confirmed with double disc diffusion method using CLSI guidelines. The isolates were screened and confirmed with double disc diffusion method using CLSI guidelines.

RESULTS

The rate of surgical site infections in our study was 8.3%. The rate of surgical site infections was higher (73.3%) in emergency surgeries than the elective surgeries. E. coli was the commonest isolate among gram negative bacilli; 33.3% isolates of E. coli were ESBL procedures. E. coli were sensitive to cefepime and ciprofloxacin and showed maximum resistance to ampicillin and cefazidime. All the E. coli were sensitive to imipenem.

KEYWORDS

Surgical Site Infections, Nosocomial, Surgeries, E. coli, ESBL.

INTRODUCTION

Surgical site infections are those infections, which occurs in the surgical incisions and involving structure adjacent to the wounds exposed during surgery.1 Surgical site infections are one of the major health problems that occur throughout the world accounting for 20-25% of nosocomial infections worldwide.2 These infections are caused by exogenous and endogenous microorganisms that enter the operative wound during the procedure.3 Surgical site infections occurs within 30 days after the postoperative procedure (Except in cases of added implants, where the duration can extend up to 1 year from operation). Surgical site infections can occur any time from zero to thirty days after the incision or the deep tissue at the operation site.4 Globally, surgical site infection rates have been reported as 2.5% to 41.9%.5 In India, the rate of surgical site infections ranges from 4-30%.6 The incidence of infected surgical wound is associated with the incidence of infected surgical wound is associated with risk factors such as preoperative care, theatre environment and postoperative care. The common cause for wound disruption are overweight, increasing age, poor nutrition, jaundice, diabetes, smoking, malignancy, presence of prior scar or radiation at the wound site.7

The common pathogenic bacteria in surgical site infections include Staphylococci, Pseudomonas, Streptococci, Enterococci, E. coli, Klebsiella, Enterobacter, Citrobacter, Acinetobacter, Proteus and S. aureus. S. aureus is present as a normal flora, can be isolated up to 60% from nose and can be readily transmitted from person to person.8 Surgical site infection is the index of the health care system of any hospital. With the increase in incidence of nosocomial infections and multidrug resistance, a meticulous and periodic surveillance of various hospital acquired infections is called for.

With an active infection control team operating in the hospital, surgical site infections are naturally one of the topmost priorities on the agenda; hence, the following study was undertaken. Diagnosis was made according to the criteria established by CDC Atlanta.8 Hence, this study was done to identify the etiological bacterial agents, antibiogram pattern and the risk factors causing surgical site infections.

MATERIALS AND METHODS

This study was conducted in a tertiary health care centre in Kanchipuram during the period of Jan to Nov 2015. The study...
population included 30 patients suffering from surgical site infections out of a total of 360, who have undergone clean contaminated surgeries and clean surgeries during the tenure of the study.

**Inclusion Criteria**
A clean contaminated and clean surgery infected with a pus discharge. Signs of sepsis (Warmth, Tenderness, Erythema, Indurations).

**Exclusion Criteria**
Wounds other than surgical wound, stitch abscess, no drainage, burns contaminated and dirty wounds.

All patients were well informed about the study and informed consent was obtained. Wounds were examined for signs and symptoms of infection in postoperative ward. When infection was suspected, the area around the wound was cleaned with saline. Exudates were collected from depth of the wound using 2 sterile swabs. A short clinical history regarding the age, sex, type of illness, diagnosis, type of surgery performed. Antibiotics given were noted.

Wound was evaluated on 3rd day, 5th day and till discharge. Patients were followed up for 30 days after surgery to identify any infection at surgical site. All the pus swabs were processed and identified as per standard methods of identification. Antibiogram was performed as per Clinical and Laboratory Standards Institute (CLSI) guidelines. Antibiotics used included ampicillin, gentamicin, ciprofloxacin, ofloxacin, imipenem, ceftizoxime, cefepime, cefazidime, cefazolin and cefotaxime.

The antibiotic discs were obtained from Hi-Media Laboratories were used. Isolates of *E. coli* were screened for Extended Spectrum β-Lactamase (ESBL) production using ceftriaxone (30 mg) and cefotaxime (30 mg). The isolates were confirmed with double disc diffusion method using Clinical and Laboratory Standards Institute (CLSI) guidelines.9

**RESULTS**
A total of 360 patients were operated during the study period. Out of which 30 patients who developed surgical site infections were enrolled in the study. Out of the 30 patients, 17 (56.6%) were males and 13 (43.3%) were females. Infection rate was 8.3%.

### Table 1: Correlation between Duration of Surgery with Culture Positivity

</tr>
<tr>
<td>Alcohol</td>
<td>7</td>
<td>23.3</td>
</tr>
</tbody>
</table>

Diabetes is the commonest risk factor followed by alcohol consumption.
Out of 23 samples which showed growth, 27 organisms were isolated. E. coli was the predominant organism followed by S. aureus.

Among 23 culture positive samples, 19 (70.37%) yielded single organism and 4 (14.8%) yielded dual organism.

Table 3: Organisms Isolated in Surgical Site Infections

Maximum resistance was seen in Ampicillin and Ceftazidime, while the least resistance was with reference to Cefepime. All isolates were sensitive to Imipenem. Among the 6 isolates of E. coli, ESBL detection was done and 2 (33.3%) isolates were ESBL producers.

DISCUSSION

The rate of surgical site infections greatly varies worldwide and from hospital to hospital from 2.5% to 41.9%. In our study the infection rate was 8.3%, which is slightly higher than Anvilar et al. (6.9%), but much lower than Patel et al. who reported 16% of surgical site infections. In our study, 17 (56.6%) were males and 13 (43.3%) were females. Similarly, Mawalla et al. reported male preponderance of surgical site infections 39 (60%) over females 26 (40%). This could be due to cigarette smoking in males. Smoking has an impact on wound healing through impairment of tissue oxygenation local hypoxia via vasoconstriction.

In our study, the rate of surgical site infections was higher in emergency surgeries, 73.3% than in elective surgeries 26.6%. This study was concordant with Patel et al. who also reported a similar preponderance of infections in emergency surgeries (24.1%) over elective surgeries (12.6%).

Emergency surgeries are often done by juniors and duty doctors and there may be a little time for preoperative procedures. In our study, the surgical site infections incidence in clean surgeries was 14 (46.6%) and clean contaminated surgeries was 16 (53.3%). This is much higher than Madhusudhan et al who reported 12% in clean contaminated and 11% in clean surgeries. The rate of surgical site infections varies from surgeon to surgeon. The skill and experience also affect the degree of contamination of surgical site through breaks in technique.

In our study, 23 (76.6%) patients showed significant growth which was slightly lower than Neelsh Naik et al. who also reported 81.1% of significant growth in their study. In our study, 23.3% showed no growth which is slightly higher than Neelsh Naik et al. who showed 18.2% samples to be culture negative. Culture negativity may be due to antibiotic therapy prior to culture of material from an apparently infected site.

In our study, the surgeries performed for more than 2 hrs. yielded culture positive and the rate of surgical site infections was also as high as 40.1%. This is concordant with Varsha et al. who also reported higher culture positivity in longer duration of surgeries 12.5%. Prolonged duration surgeries results in increased exposure of operation site to air, prolonged trauma, stress of prolonged anaesthesia and sometimes blood loss.

In our study, diabetes constitutes an important predisposing factor for surgical site infections followed by alcoholism and smoking. This is concordant with study done by Ramesh et al. who also reported diabetes and alcohol as important risk factors for surgical site infections. Similar findings were reported by S.M. Patel et al. who reported 36.4% of surgical site infections in patients with diabetes mellitus.

In our study among 23 culture positive isolates, 19 (70.37%) yielded single organism. This is lower than Neelsh Naik et al. who reported a corresponding yield of 92.16%. In our study, 4 (14.8%) dual organisms which is much higher than Neelsh Naik et al. who reported 7.84% of dual organisms causing surgical site infections.

S. aureus is the predominant isolate among gram positive and in gram negative E. coli was the most commonly isolated. This is concordant with Ramesh et al. who has also isolated a similar pattern of organisms.

It has been found that in clean surgeries, S. aureus from the exogenous environment or the patient’s skin flora is the usual pathogen. Whereas in other categories of surgical procedure clean contaminated the polymicrobial flora closely resembling the normal endogenous microflora of the affected site is the frequently isolated pathogen.

The organisms most frequently involved in surgical site infections change from time to time and from place to place and so does their sensitivity to various antibiotics.

Among the gram negatives, E. coli was the commonest isolate and was sensitive to cefepime, ciprofloxacin and showed maximum resistance to ampicillin and ceftazidime. All the E. coli isolates were sensitive to imipenem.

Among the 6 isolates of E. coli, ESBL detection was done and 2 (33.3%) isolates were ESBL producers. This is much higher than Saraswathi et al. who had isolated 14.2% of ESBL in their study. Findings from this study on surgical site infections suggests that the introduction of evidence based antibiotic policy in the hospital is a must.

CONCLUSION

The rate of surgical site infections in our study was 8.3%. The rate of surgical site infections were high in emergency surgeries 73.3% as compared to elective surgeries. The incidence of surgical site infections was more (40.1%) in long duration surgeries performed for more than 2 hrs. Diabetes

Table 4: Organisms Isolated in Surgical Site Infections
constitutes an important predisposing factor followed by smoking and alcohol.

E. coli was the commonest isolate among gram negative bacilli and 33.3% isolates of E. coli were ESBL procedures.

Surgical site infections were more in diabetic populations. This indicates that underlying risk factor needs to be carefully evaluated in treating surgical site infections.

Infection control measures such as active surveillance of surgical site infections, compliance observation and instruction/training of healthcare workers, adherence to preoperative antibiotic prophylaxis, maintenance of normothermia and blood glucose control are essential in order to prevent surgical site infections.
