ABSTRACT

BACKGROUND

Pre-diabetes is the clinical stage in which blood glucose level of a person is higher than normal, but not yet high enough to be classed as diabetes. Without lifestyle changes to improve their health, most of the people with pre-diabetes will develop Type-2 diabetes within five years.

AIMS AND OBJECTIVES

Progression of type-2 diabetes from pre-diabetic condition may involve various inflammatory mechanisms, which induce insulin resistance and beta cells dysfunction. Obesity, particularly visceral obesity results in pro-inflammatory state starting in the metabolic cells (Adipocytes, hepatocytes and myocytes) and also recruiting immune cells with the consequent release of pro-inflammatory cytokines - Tumour necrosis factor α/TNF-α, Interleukins-6/IL-6, etc. To combat internal harm of inflammations, liver cells produce high sensitivity C-reactive protein/hS-CRP. We have conducted this study to estimate inflammatory markers in pre-diabetics to identify the individuals who are at high risk, to prevent development of Type 2 diabetes and other complications related to the disease.

MATERIALS AND METHODS

In our present study we included 60 pre-diabetic subjects, selected from Medicine OPD of KPC Medical College on the basis of Impaired Fasting Glucose 100-125 mg/dL, Impaired Glucose Tolerance or two-hour glucose levels on 75-g oral glucose tolerance test 140-199 mg/dL, waist circumference: male >90 cm, female >80 cm, BMI ≥25, BP >130/85 mmHg, Triglycerides >200 or HDL <35 and HBA1C (5.7%-6.4%); 60 normo-glycaemic subjects are also taken as controls. Overnight fasting venous blood samples are collected from cases and controls to estimate fasting blood glucose, fasting insulin, TNF-α, IL-6 and hs-CRP. We have calculated HOMA-IR and correlated it with the findings.

RESULTS

We have found that HOMA-IR of pre-diabetic study group is significantly correlated with TNF-α (r=0.925) and IL-6 (r=0.766) respectively. There is also significant positive correlation in between the TNF-α and hs-CRP of pre-diabetics in this study (r=0.831).

CONCLUSIONS

These results suggest that TNF-α, IL-6 as well as hs-CRP increase in pre-diabetic condition and systemic inflammations play an important role in the progression of pre-diabetes to diabetes and other complications.

KEYWORDS

Pre-Diabetes, Pro-inflammatory Cytokines, TNF-α, IL-6, hs-CRP, HOMA-IR, Insulin Resistance, Type-2 Diabetes.

INTRODUCTION

Pre-diabetic individuals are diagnosed by the Impaired Fasting Glaecma (IFG), having higher than normal glucose level after a period of fasting and Impaired Glucose Tolerance (IGT), having higher than normal post-prandial glucose level and also glycated haemoglobin (HbA1C) in the range 5.7-6.4.[1] According to the criteria of World Health Organisation (WHO), Impaired Fasting Glucose is defined as Fasting plasma glucose level of 6.1 mM/l - 6.9 mM/l (110-125 mg/dL).[2]

The American Diabetes Association (ADA) since 2003 uses a slightly different range for Impaired Fasting Glucose of 5.6 mM/l - 6.9 mM/l (100-125 mg/dL). According to World Health Organization and the American Diabetes Association, both Impaired Glucose Tolerance is defined as two-hour glucose levels of 7.8 - 11.0 mM/l (140-199 mg per dL) on 75-g oral glucose tolerance test.[3,4] Pre-diabetic individuals are at higher risk for developing type 2 diabetes and also different complications related to this disease. High risk group among pre-diabetics who have age ≥45 years, family history of diabetes (Parent or sibling), history of gestational diabetes, infant born with birth weight >9 lb (4 kg), high risk ethnic group, known vascular disease, markers of insulin resistance (PCOS, Acanthosis Nigricans), etc.[5,6]

Other risk factors of pre-diabetic persons for development Type 2 diabetes and its related complications are: triglycerides >200 mg/dL or HDL <35 mg/dL, overweight or obesity (Body Mass Index or BMI >25), hypertension (BP >135/85 mmHg), low-grade inflammation with elevated pro-inflammatory cytokines like Interleukins (IL-1, IL-6, etc.)[7,8] and Tumour Necrosis Factor Alfa (TNF-α).
elevated high sensitivity C-Reactive protein (hs-CRP), prothrombotic state with increased PAI-1 and Fibrinogen, increased uric acid levels (Caused by dietary fructose) and others.\(^9\)

The link between obesity and inflammation has been derived from the finding that pro-inflammatory cytokines are over expressed in obesity.\(^10\) Adipose tissue is a heterogeneous mix of adipocytes, stromal pre-adipocytes, immune cells and endothelium and it can respond rapidly and dynamically to alterations in nutrient excess through adipocyte hypertrophy and hyperplasia.\(^10,11,12\) With obesity and progressive adipocyte enlargement, the blood supply to adipocytes may be reduced with consequent hypoxia. Hypoxia has been proposed to be an inciting aetiology of necrosis and macrophage infiltration into adipose tissue that leads to an overproduction of pro-inflammatory factors.\(^12\)

In obese men and women if compared with lean controls, adipose tissue and liver display an increased activation of three kinases able to induce the expression of inflammatory cytokines.\(^13\) The C-Jun N-terminal Kinase (JNK), the Inhibitor of K Kinase (IKK) and the Protein Kinase C (PKC).\(^11,14\) In the same metabolic tissues, the inflamasome and the Toll-Like Receptors (TLRs) of the innate immune system are also activated.\(^14\) Nutrients or inflammatory signals may activate the TLRs pathways and downstream JNK, IKK and PKC.\(^11,14,15\) These kinases regulate downstream transcriptional programs through the transcription factors activator protein-1 (AP-1), NF-κB and Interferon Regulatory Factor (IRF), inducing up regulation of inflammatory mediator gene expression. The increase in cytokines exacerbates receptor activation by establishing a positive feedback loop of inflammation and the inhibitory signalling of metabolic pathways.\(^15\)

To combat internal harm of inflammations, liver cells produce high sensitivity C-reactive protein/hs-CRP in response to TNF-α and IL-6 produced by adipocytes as well as macrophages (Vide Figure 1).

---

**AIMS AND OBJECTIVES**

In last few years, numerous studies have shown low-grade inflammation in pre-diabetic state is associated with high risk of developing type-2 diabetes. Furthermore, now-a-days it is accepted that chronic subclinical inflammation is a part of the insulin resistance syndrome.\(^15\) The pancreatic beta cells can no longer produce enough insulin to overcome insulin resistance, causing blood glucose rise above the normal range, i.e. prolonged low-grade inflammation during pre-diabetic state facilitate onset of diabetes and its related complications.\(^16\) Epidemiological evidence also supports the facts that pro-inflammatory markers predict the development of diabetes and glucose disorder.\(^17,18\) However, there are also some studies which do not support this.

So we did a prospective, cross-sectional, descriptive and observational hospital-based study in a reference population of pre-diabetic individuals irrespective of age and sex to identify those individuals at high risk early, so that their
lifestyle interventions and treatment may prevent the development of Type 2 Diabetes and/or Cardiovascular disease as well as the long-term complications affecting the eyes, kidneys and nervous system and also to prevent cerebrovascular accident.

MATERIALS AND METHODS
The study was carried out at the outpatient clinic of Department of Medicine in KPC Medical College and Hospital, Jadavpur, Kolkata, for a period of one year from inception. Patients were chosen from outdoor of Medicine Department of KPC Hospital. Our study group comprise of 60 pre-diabetics patients, age within 35–65 years having IFG, IGT and HbA1C 5.7–6.4 with/without family history of diabetes; 60 normo-glycaemic healthy persons who were in the same age group as our study group also taken as control. All biochemical tests were carried out at the Department of Biochemistry in KPC Medical College and Hospital, Kolkata.

Patients with history of Acute myocardial infarction, Heavy injuries, Acute or Chronic renal failure, Hyperglycaemic crisis (FBG ≥250 mg/dL or PPBG ≥300 mg/dL or HbA1c >10%), severe hypertriglyceridemia (TG >400 mg/dL) were excluded from the study. Patients were selected after taking their interviews and history and also by clinical examination. Important clinical examinations which were included in our study were – patient’s Height, Weight, Skin Tag, Signs of Pallor, Oedema, Jaundice, Cyanosis, clubbing, palpable Neck glands and engorged Neck veins, presence of Acanthosis nigricans, etc. We also measured Waist circumferences, Hip circumferences and Neck circumferences of the patients.

Their essential parameters like pulse, BP, Temperature were recorded. Overnight (12 hours) fasting venous blood samples are collected from cases and controls for the estimation of fasting blood glucose, fasting insulin, TNF-α, IL-6 and hs-CRP. (Fasting insulin, TNF-α, IL-6 were estimated by their respective ELISA kit and hs-CRP is estimated by latex-agglutination test in Microbiology Department of KPC Medical College).

RESULTS AND ANALYSIS
A total of 60 pre-diabetic persons were included in this study, which comprised of 24 males and 36 females in a range of 35–65 years; 60 healthy individuals of same age were also taken as controls, of them 32 were male and 28 were female. All the biochemical parameters like fasting blood glucose, fasting insulin, TNF-α, IL-6, hs-CRP were elevated at significant level in pre-diabetic study group than that of healthy controls. (Vide Table 1 and 2, Figure 2 and 3). We have calculated HOMA-IR, \[\text{HOMA-IR} = \frac{\text{Glucose} \times \text{Insulin}}{22.5}\] (Glucose in Molar Units mmol/L),\(^{20}\) or \[\text{HOMA-IR} = \frac{\text{Glucose} \times \text{Insulin}}{405}\] (Glucose in mass units mg/dL),\(^{21}\) and correlated it statistically with other findings by Student’s T-test.

In this study, it is found that HOMA-IR is significantly (Positively) correlated with two pro-inflammatory parameters TNF-α and IL-6 in pre-diabetic study group. Correlation coefficient in between HOMA-IR and TNF-α is, \(r = 0.925\), which is very highly significant at \(p < 0.00001\) (Vide Figure 4).

IL-6 of pre-diabetics is also significantly and positively correlated with their HOMA-IR. Correlation coefficient \(r = 0.766\) at \(p < 0.00001\) (Vide Figure 5).
farming blood glucose, fasting insulin, TNF-α, IL-6 and hs-CRP are significantly increased in pre-diabetic study group than the healthy controls. We have calculated HOMA-IR from their fasting blood glucose, fasting insulin which was correlated with both TNF-α (Correlation coefficient r=0.925) and IL-6 (Correlation coefficient r=0.766) significantly and positively in pre-diabetic individuals.

TNF-α is also significantly and positively correlated with hs-CRP (correlation coefficient r=0.831) in pre-diabetics. So the results from this study confirmed that inflammatory markers (TNF-α, IL-6) are increased in pre-diabetic condition and to combat internal harm, inflammation produces highly sensitivity C-reactive protein (hs-CRP).

CONCLUSION

It is already known that inflammation is part of the body’s immune system, which triggers a defence response to harmful stimuli.[22] The body reacts to injury by sending specialized blood cells to damaged areas where they attack “Invaders” and clean up dead and dying cells.[22,23] In the case of inflammation and Pre-Diabetes, the “Invader” is thought to be excess levels of insulin, which can be caused by the imbalance of blood glucose and insulin called Insulin Resistance.[23] Obese subjects subsist in a heightened low-grade systemic inflammatory milieu as overweight and they exhibit central adiposity (increased waist circumference), the low-grade systemic inflammation is possibly resulted by an expanded visceral adipose tissue compartment.[22,23] An increased mass of dysfunctional adipose tissue in ectopic locations influences the overall total body metabolism with secretions that have auto, para and endocrine effects. Macrophage infiltration in the visceral adipose tissue generates hepatic insulin resistance and the association of chronic inflammation.[24,25]

Numerous studies have supported the fact that prolonged low-grade inflammation with raised inflammatory markers during pre-diabetic state facilitate onset of Type-2 Diabetes, beta-cell dysfunction and Insulin Resistance.[25,26] The changeover from the early metabolic abnormalities that antedate diabetes, Impaired Fasting Glucose (IFG) and Impaired Glucose Tolerance (IGT) to diabetes may take many years, but current estimates indicate that most individuals with these pre-diabetic states eventually end up with diabetes. Individuals who are older, overweight, having sedentary life-style and have other risk factors of diabetes are more likely to progress.[26,27]

Thus to conclude we can say that our present study may help to identify high-risked pre-diabetic individuals, so that their life-style intervention, change of diet, weight loss and proper treatment may prevent development of Type-2 diabetes and other complications related to this disease.
