ABSTRACT

BACKGROUND
COPD is an epidemic of modern society. It is one of the major causes of morbidity and mortality in the world. It is a well-known thought that one of the main complication of COPD is Pulmonary Embolism. It is mainly because of changes in platelet count and morphology under the chronic influence of inflammatory cytokines. [1,2,3] Meanwhile, this can also be taken as a parameter for determining severity of COPD. [4]

MATERIALS AND METHODS
The descriptive study of 200 patients diagnosed with COPD, admitted in General Medicine Wards at Government Rajaji Hospital, Madurai were selected. Mean platelet volume [5] of each patient was found out with 24 hours of admission. Spirometry was done to assess the severity of COPD and correlation was established between the two.

Statistical Analysis: Correlation coefficient.
Settings and Design: Correlation study.

RESULTS
From the study, it was found that COPD is more common after 40 years in males, and is strongly associated with smoking. It was also found that there is a strong correlation between spirometry values and mean platelet volume, i.e. when FEV1% and FEV1/FVC ratio decreases, the MPV also decreases and when FEV1% and FEV1/FVC ratio decreases, the platelet count increases.

CONCLUSION
MPV was significantly decreased in patients with acute exacerbation of COPD [6,7,8] when compared with stable phase of COPD. FEV1, FEV1/FVC are the main parameters in PFT [9] to determine the severity. MPV in patients with COPD was found to be independent of age, sex, family history, COPD, systemic hypertension and diabetes mellitus. While smoking is an important risk factor. When MPV decreased in severe COPD, platelet count increased. [10] MPV can be used as a prognostic marker for COPD. There was high negative correlation between platelet count and MPV. [11] There was a very high positive correlation between MPV and severity of COPD.

KEYWORDS
Mean Platelet Volume, Platelet Count, COPD, Pulmonary Embolism.

BACKGROUND
COPD is an epidemic of modern society. COPD is one of the major causes of morbidity and mortality in the world. Despite the impressive strides in diagnosis and management over the past three decades, COPD continues to be a major public health problem in industrialised world and is becoming an increasingly important health problem in developing countries. Because COPD may strike an individual during the most productive years, it can have profoundly deleterious psychosocial and economic ramifications. It is a well-known thought that one of the main complications of COPD is Pulmonary Embolism. It is mainly because of changes in platelet count and morphology under the chronic influence of inflammatory cytokines. Meanwhile, this can also be taken as a parameter for determining severity of COPD. Wang et al (2013) stated that there is decrease in mean platelet volume [10,12] when there is an exacerbation of COPD. Initially, there is an increase in mean platelet volume when there is stable phase of COPD.

Ulasli et al (2012) suggested that mean platelet volume can be used as a negative acute phase reactant. [13] But it requires further more studies to prove this result. Thus, the role of platelet volume as a predictor for severity of COPD is unresolved and further studies are definitely needed. This study will help to confirm or refute the published reports on platelet volume in COPD.

MATERIALS AND METHODS
Study Population
• This descriptive study was conducted among 200 patients diagnosed with COPD admitted in General Medicine wards at Government Rajaji Hospital, Madurai.
Inclusion Criteria
- Patients diagnosed with COPD using GOLD [27] criteria.
- Age above 40 yrs.
- Gender: Both Male and Female.

Exclusion Criteria
- Diabetes mellitus.
- HTN.
- Asthma.
- Bronchiectasis.
- Active pulmonary tuberculosis.
- Coronary artery disease.\(^{(11)}\)
- Systemic inflammatory diseases.
- Pulmonary thromboembolism.
- Medical treatment with anticoagulant statins.\(^{(14)}\)
  angiotensin-converting enzyme inhibitors, acetylsalicylic acid or clopidogrel.

Study Protocol
200 patients diagnosed with COPD, admitted in General medicine wards at Government Rajaji Hospital, Madurai were selected. Selected socio-economic, clinical and laboratory data\(^{(15)}\) were collected from the patients recorded in a proforma. 2 mL of blood was withdrawn by venepuncture from the patients within 24 hrs. of admission to the hospital for assessing MPV (mean platelet volume). The instrument used for analysis was Cobas Micros OT 18 automated haematological analyser.\(^{(5,16)}\) Spirometry was done for every patient for diagnosis of COPD and for assessing the severity.

Statistical Analysis
The data collected during the study was formulated into a master chart in Microsoft Office Excel and statistical analysis was done with the help of computer using statistical software package SPSS V.17 for windows. Using this software, frequencies, range, mean, standard deviation and percentages were calculated. The statistical analysis was done by the calculation of correlation coefficient between the spirometry and MPV.\(^{(17)}\)

The average values of mean platelet volume and the standard deviation were calculated in the four groups namely control population with mild, moderate, severe and very severe COPD. To establish that the difference in MPV between these groups is statistically significant, ANOVA (analysis of variance) was carried out. A ‘p’ value of < 0.05 was considered statistically significant.

RESULTS
In our study 30.5% cases (61) were between 41 - 50 years, 31.5% cases (63) were between 51 - 60 years, 17.5% cases (35) were between 61 - 70 years, 16% cases (32) were between 71- 80 years and 4.5% cases (9) were between >80 years. As we all know, COPD is more common in males.\(^{(18)}\) Our study also reveals the same- males 72% and females 28%. As well documented in other studies, our study also clearly proves the fact of increased incidence in smokers.\(^{(19)}\) In our study, 144 cases (72%) out of 200 cases were smokers. Out of this, 21% cases had < 20 pack years, 19.5% cases had 20 - 29 pack years, 17.5% cases had 30 - 39 pack years, 12.5% cases had >40 pack years. As we all know, there is no significant relation between SHT, T2DM and COPD. Our study showed 53.5% cases (107) are hypertensives and 40% (80) cases are diabetics.

Spirometry Values and Severity of COPD
- FEV1 < 30% (very severe) - 4.5% cases (9)
- FEV1 30 - 49% (severe) - 32.5% cases (65)
- FEV1 50 - 79% (moderate) - 46% cases (92)

FEV1/FVC Ratio in COPD- The results of FEV1/FVC ratio in COPD in our study is similar to FEV1 values in COPD.

Platelet Count and COPD
In our study, platelet count > 3 lakhs are 27.5% cases, 2-3 lakhs are 35.5% cases and 1-2 lakhs are 37% cases. In our study, 13.5% cases had MPV < 8 fL, 23.5% cases had 8-9 fL, 39.5% cases had 9-10 fL, 23.5% cases had >10 fL. As per GOLD criteria, FEV1 decreases and FEV1/FVC ratio also decreases when there is increase in severity of COPD. In our study also, it proved the same. If FEV1 < 30%, the FEV1/FVC is 0.48 and if FEV = 80%, the FEV1/FVC is 0.7. In our study-
- In very severe COPD (FEV1 < 30%), the MPV is 7.78 fL
- In severe COPD (FEV1 30% - 49%), the MPV is 8.31 fL
- In moderate COPD (FEV1 50% - 79%), the MPV is 9.73 fL
- In mild COPD (FEV1 < 30%), the MPV is 10.89 fL

Thus, in severe COPD Mean Platelet Volume is decreased. The collected values of FEV1, FEV1/FVC ratio, MPV and platelet count are analysed for finding significance between each other. Since there is no controls in our study, correlation coefficient is used for finding significance.

### Table 1

<table>

</tbody>
</table>
It means that,

- When FEV1%, FEV1/ FVC ratio decreases, the MPV also decreases.
- When FEV1%, FEV1/ FVC ratio decreases, the platelet count increases.

DISCUSSION

COPD is a major cause of morbidity and mortality in developed countries and is becoming a major problem in developing countries like India. Endogenous and exogenous risk factors like smoking, sex, diabetes mellitus and systemic hypertension significantly increase the progression of COPD. However, they only explain a part of the cases and there may be other relevant risk factors which need to be identified. Large platelets are more reactive, produce more thrombotic factors and aggregate more easily. Documented changes in mean platelet volume in COPD. But all these studies are conducted in limited sample size. So in this study, an attempt was made to find out if any association existed between the platelet size and severity of COPD among Indian population as reports are scanty.

In the study, the ages of the cases are above 40 years. The most number of cases fell between 51 - 60 years. This pattern corresponds to the pattern reported in India, which is as follows. COPD appears decade earlier compared with the age incidence in developed countries and the peak period is attained between 51 - 60 years. In the present study, the relationship between age and MPV was not statistically significant, whereas Funaik et al (1994) found that MPV was significantly increased in patients of advanced age and it was statistically significant. But MPV decreases with age. But our study did not confirm any of the observations made by the above two workers. COPD is common in males. It is mainly due to environmental factors and deleterious effects of smoking. Females generally are affected after menopause. In the present study, MPV was independent of genders. This is in parallel with the observation. It has been noted that smoking is an important factor, which plays a major role in progression and exacerbation of COPD.

In the present study, no statistical relationship was observed between systemic hypertension and MPV. Bath et al (1996) also observed the same in their study. In contrast, Osuna et al (1998) observed a higher MPV in those with systemic hypertension. MPV in patients with diabetes mellitus did not vary from those without diabetes mellitus. Sharpe et al (1993) stated that MPV was significantly increased in diabetics compared with non-diabetics. They stated that since platelet size is a determinant of platelet function with larger platelets being more reactive per unit volume, the platelets might play a role in micro- and macro-vascular complications of diabetes mellitus. The fact that in our study no relationship was observed may be due to inflammatory cytokines in COPD.

As per GOLD guidelines (2010) for defining COPD, FEV1 should be ≤ 80%. In our study, most of the cases having FEV1 values ranging from 30% - 79%. Hence, there is a high correlation between severity of COPD and FEV1. Our study has statistically documented this fact. The FEV1/ FVC ratio is also one of the criteria for defining COPD. In our study, the FEV1/ FVC ratio ranges from 0.5 - 0.69. Thus, statistically proving that there is a relation between FEV1/ FVC ratio and severity of COPD.
