2Senior Resident, Department of Respiratory Medicine, Sri Ramachandra Medical College and Research Institute, SRIHER, Tamilnadu, India.
3Professor, Department of Respiratory Medicine, Sri Ramachandra Medical College and Research Institute, SRIHER, Tamilnadu, India.
4Professor, Department of Respiratory Medicine, Saveetha Medical College and Hospital, Kanchipuram, Tamilnadu, India.
5Assistant Professor, Department of Respiratory Medicine, Saveetha Medical College and Hospital, Kanchipuram, Tamilnadu, India.

PRESENTATION OF THE CASE
A 40 year old male patient, farmer by occupation, presented with complaints of abdominal pain on and off for the past 20 days, increased for the past 2 days over the left lumbar region, colicky pain, non-radiating, associated with burning micturition, no complaints of nausea, vomiting, constipation, loose stools, fever, loss of weight, loss of appetite, shortness of breath, cough with expectoration or chest pain. No co-morbidities, no history of smoking or alcoholism.4

Systemic Examination

Rs- bilateral normal vesicular breath sounds, no added sounds, CVS- S1S2 heard, no murmurs, per abdomen –mild lumbar tenderness present over the left side, CNS- no focal neurological deficit.

CLINICAL DIAGNOSIS
On examination- well-built and nourished, no pallor, icterus, clubbing, cyanosis, lymphadenopathy or pedal oedema. Vitals- Temperature-afibrile, pulse rate-63/min, respiratory rate-20/min, blood pressure- 120/80 mmHg, SPO2-84% at room air.

DIFFERENTIAL DIAGNOSIS
1. Cyanotic congenital heart disease (Right to Left Shunt).
2. Pulmonary thromboembolism.
4. Sulfhaemoglobinemia.5

PATHOLOGICAL DISCUSSION
Hb- 14.6 gm/dl, total count- 5500 cells/cu.mm, RFT, LFT- with in normal limits, peripheral smear-normal study, Chest X-ray –normal,
abG at room air-PH-7.40, PCO2-47.6 mmHg, PO2- 67.1 mmHg, HCO3-28.9. 2D-ECHO-Normal chamber dimensions, PAP-20 mmHg, EF-64%.
PFT and diffusion studies were found to be normal. Holter monitoring showed no significant abnormalities. 6 minute walk test showed no desaturation from baseline of 84%
CT –KUB showed left distal ureteric calculi causing mild hydroureronephrosis. Patient was planned to undergo lithotripsy and left DJ stenting.

Pulmonologist and cardiologist opinion was sought in view of persistent hypoxemia.
Cardiovascular and respiratory evaluation were found to be normal. On persistent history, patient denies history of exertional dyspnoea, on retrospective history patient gave history of exposure to pesticides (Bifenthrin, cartap hydrochloride, kasugamycin, cypermethrin) used in agricultural field for the past 7 years, no family history of cyanosis, patient suspected to have haemoglobinopathies and evaluated further.

**Chromatogram**

Normal study, carboxyhaemoglobin-7% (Reference value-12%), methaemoglobin-26.4 (Ref. value < 1.5), reticulocyte count- 2.1.

Patient was diagnosed to have methemoglobinemia patient was planned for methylene blue therapy, for which G6PD deficiency was ruled out.

G6PD - 11.3 U/gHb (ref-6.4-18.8).

Direct and indirect coombs test was negative.

**DISCUSSION OF MANAGEMENT**

Methaemoglobinemia is a condition characterised by increased quantities of haemoglobin in which the iron of haeme is oxidised to Ferric form.

Methaemoglobin has got decreased affinity for oxygen and so decreased availability of oxygen to the tissues.

**Types**

**Congenital**

Due to deficiency of enzyme nicotinamide adenine dinucleotide NADH cytochrome b5 reductase, which helps in conversion of methaemoglobin to functional haemoglobin.

**Congenital type is again classified as** –

1. Erythrocytic - here the soluble form of enzyme is deficient only in the erythrocytes.
2. Generalised - where the membrane bound form of enzyme is deficient in all tissues causing severe developmental abnormalities.

**Acquired**

Due to exposure to drugs and chemicals commonly used in cardiac and anaesthetic procedures, which oxidizes haemoglobin to form methaemoglobin.

Drugs causing methaemoglobinemia are acetanilide, alloxan, aniline, arsine, benzene derivatives, bivalent copper, bismuth, bupivacaine, chorates, chloroquine, chromates, dapsone, dimethyl sulfoxide, dinitrophenol, exhaust fumes, ferric cyanide, flutamide, hydraxylamine, lidocaine, metoclopramide, naphthalene, nitrates, nitrofurans, nitroglycerin, sodium nitroprusside, paraquat, phenacetin, phenol, phenytoin, rifampin, sulphasalazine and sulphonamides

Cardiologist opinion was sought in view of methylene blue infusion.

Patient was given methylene blue infusion of 1 mg/kg body weight over 20 mins, SPO2 improved to 99% at room air.

During and post procedure vitals monitoring was found to be normal.

**Follow-Up**

Patient was reviewed after 1 month, and repeat saturation was found to be 94% at room air. Repeat methaemoglobin levels were found to be 16.2%.

Patient was planned for one other methylene blue infusion on follow up.

Severe acute methaemoglobinemia requires immediate therapy, whereas chronic asymptomatic patients will not
Methylene blue (1 mg/kg/body weight) - contraindicated in G6PD deficiency.

Others include exchange transfusion and hyperbaric oxygen therapy, where methylene blue is contraindicated or ineffective. Ascorbic acid, riboflavin, N-acetyl-cysteine are the other supportive drugs given.

**FINAL DIAGNOSIS**
Methaemoglobinemia.
