A COMPARATIVE STUDY OF ABO BLOOD GROUPS AND SECRETOR STATUS IN ISCHAEMIC HEART DISEASE PATIENTS IN KADAPA CITY

Parveen Shaik1, A. Chandra Sekhar2

1Assistant Professor, Department of Physiology, RIMS, Kadapa, Andhra Pradesh, India.
2Associate Professor and HOD I/C, Department of Physiology, RIMS, Kadapa, Andhra Pradesh, India.

ABSTRACT

BACKGROUND

Obesity, hypertension, diabetes mellitus, dyslipidaemia, smoking, stress, sedentary lifestyle and genetic factors are some well-known risk factors for Ischaemic Heart Disease (IHD). The ABO blood groups and secretor status may be linked to IHD and its risk factors. Aim- To study the correlation between ABO blood groups and secretor status in the IHD patients in the city of Kadapa.

MATERIALS AND METHODS

This study was conducted in Department of Physiology, RIMS Medical College, from August 2015 to January 2016. This is a case control study and selection of cases and controls was done by simple random sampling. 600 patients with IHD diagnosed based on the electrocardiograms were chosen from Cardiology Unit, RIMS General Hospital, Kadapa. 600 volunteer blood donor’s age and sex matched with no evidence of any disease were included. Blood group estimation was done by slide agglutination method and secretor status was done by indirect haemagglutination method. The sample size required was taken for convenience. Chi-square test and p-value were used for statistical analysis by SPSS software version 17.

RESULTS

The frequency distribution among IHD patients was maximum in B group (45.6 %) followed by O group (21.6%), A group (19.9%) and AB group (12.7%). Among the cases, 21.5% were secretors and 78.5% were non-secretors and there was a significant association of non-secretors with IHD with Chi-square value of 401.3 and a p-value of 0.00000.

CONCLUSION

The results of this study conclude that B group non-secretors are more prone to IHD in the city of Kadapa.

KEY WORDS

ABO Blood Groups, Secretor Status, Ischaemic Heart Disease.

BACKGROUND

At the turn of 20th century, Karl Landsteiner first described the existence of serological differences between individuals and stated that people of the world, irrespective of their race can be divided into four groups depending on the substances present on the surface of their red blood cells. In 1901, he grouped the individuals into A, B, AB and O. The discovery of the iso-agglutinogens was a milestone in the field of medicine. Karl Landsteiner received the Nobel prize for his discovery of the ABO system of blood groups.(1)

The A, B and O genes all locate together at 9q34.1 - q34.2. The genes of the ABO system do not encode directly for the antigens, but encode for enzymes that add specific sugars to the red cell membrane. These sugars are the ABO red cell antigens that are detectable with serological testing. The A gene codes for the transferase α(1,2) N-acetylgalactosamine transferase and the B gene codes for transferase α(2,3) galactosyl transferase and O allele encodes for non-functional transferase.(2)

The ABH antigens are found not only on red cells, but also on other cells in the most body fluids and on the cell membranes of tissues such as intestine, urothelium and vascular endothelium. The expression of ABH antigens into body fluids is controlled by the Sese genes and they are located on chromosome 19q13.3.(3)

There is some evidence that ABO blood groups may be associated with certain diseases. Gastric cancer has been reported to be more prevalent in individuals with blood group A, but peptic ulcer is more often seen in those with blood group O.(4)

The term ABH secretor refers to secretion of ABO blood group antigens in fluids such as saliva, sweat, tears, semen and serum. Approximately, 80% of people are secretors (SeSe or Sese). People who do not secrete their blood type antigen in their secretions are termed non-secretors. About 15% of the population are non-secretors. For example -

- O Group secrete H antigens.
- A group secrete A and H antigens.
- B group secrete B and H antigens.
- AB group secrete A, B and H antigens.(5)

IHD is a condition in which there is an inadequate supply of blood and oxygen to a portion of the myocardium. It
typically occurs when there is an imbalance between myocardial oxygen supply and demand. IHD causes more deaths and disability and incurs greater economic costs than any other illness in the developed world. Risk factors that are associated with IHD are high fat and energy rich diet, smoking, sedentary lifestyle, obesity, insulin resistance and type II diabetes mellitus. The way to reduce Coronary Artery Disease (CAD) risk include eating a healthy diet, regular exercise, maintaining a healthy weight and not smoking.

MATERIALS AND METHODS
Study Design / Method of Study
This is a case-control study, which is a type of observational study.

Method of Sampling
Simple random sampling was used among cases and controls.

This study was conducted between August 2015 and January 2016 in RIMS General Hospital, Kadapa, Andhra Pradesh state, India. Case sheets were filled for the IHD patients and control subjects to obtain their medical history and socio-demographic parameters (Age, sex, educational status, occupation, blood groups and willingness to participate in the study). The sample size required was taken for convenience.

Cases
The study included a total of 600 IHD patients. The IHD was diagnosed based on ECG taken who came to Cardiology unit, RIMS General Hospital, Kadapa complaining of chest pain. Patients were selected at random after admission from ICCU (Intensive Coronary Care Unit). Patients of both sexes were selected in the age group of 25 - 65 years. 600 patients were studied, among them 444 were males and 156 were females.

Controls
600 Control subjects were recruited for this study from the healthy volunteer blood donors with no evidence of any disease who came to blood bank, RIMS General Hospital, Kadapa. Both males and females of ages ranging from 25 to 65 years were recruited. Among 600 controls, 412 were males and 188 were females.

Blood Group Determination
Blood group was determined by slide agglutination technique.

Principle
The surface of the red cell membrane contains genetically determined antigens called agglutinogens, while plasma contains antibodies called agglutinins. To determine the blood group of a person, his/her red cells are made to react with sera containing agglutinins. The slide is then examined under a microscope to detect the presence or absence of clumping and haemolysis of red cells that occurs as a result of antigen-antibody reaction.

Cases
Blood Group Determination was performed by slide agglutination test. It was determined by Haemagglutination inhibition technique. This is a case-control study, which is a type of observational study.

Determination of Secretor Status
It is determined by Haemagglutination inhibition technique.

Materials
Antisera, slide, lancet, compound microscope.

Procedure
Under aseptic precautions, the pulp of the ring finger was pricked by a sterile lancet and one drop of anti-A was placed on one side of a microscopic slide and labelled as A. One drop of anti-B was placed on the other side of the same slide and labelled as B. A drop of blood was added to each drop of antiserum. Blood groups were determined as follows:

- **Agglutination in slide A**: Blood Group A
- **Agglutination in slide B**: Blood Group B
- **Agglutination in both slides**: Blood Group AB
- **Agglutination in neither slide**: Blood Group O

Determination of Secretor Status

It is determined by Haemagglutination inhibition technique.

1. **Materials**
   - Antisera, slide, lancet, compound microscope.

2. **Procedure**
   - Under aseptic precautions, the pulp of the ring finger was pricked by a sterile lancet and one drop of anti-A was placed on one side of a microscopic slide and labelled as A. One drop of anti-B was placed on the other side of the same slide and labelled as B. A drop of blood was added to each drop of antiserum. Blood groups were determined as follows:
     - **Agglutination in slide A**: Blood Group A
     - **Agglutination in slide B**: Blood Group B
     - **Agglutination in both slides**: Blood Group AB
     - **Agglutination in neither slide**: Blood Group O

3. **Materials**
   - Antiserum (Anti-A, Anti-B, Anti-H)
   - Diluted and processed saliva
   - Test tube rack with tubes
   - Pipette
   - Microscope
   - Slide
   - Centrifuge
   - Hot water bath
   - Sterile containers

4. **Procedure**
   - **Saliva** was collected at room temperature between 11 a.m. and 12 noon and tests were carried out between 12 noon and 4 p.m.

5. **Preparation of 5% Red Cell Suspension**
   - The freshly collected blood in an EDTA bottle was transferred into a small glass tube and centrifuged at a speed of 3000 rpm for 15 minutes to pack the red cells. The supernatant plasma was separated as much as possible from the cells and replaced by sterile isotonic saline. This mixture was centrifuged again and the supernatant separated from the cells. This procedure was repeated 3 to 4 times to wash the red blood cells. Washing of the red blood cells was done to remove any antibody present on the cells.

   - After the last washing, the supernatant was removed and one drop of packed red cells was mixed with 19 drops of saline.
normal saline to prepare a 5% red cell suspension in isotonic saline.

**b) Collection and Processing of Saliva**
Saliva was collected at room temperature in sterile disposable containers. The patient was instructed to wash the mouth and drink a glass of water. One millilitre of saliva was collected in a sterile plastic bottle and transferred to a sterile test tube. The tube was then kept in a boiling water bath (100°C) for twenty minutes. Saliva was boiled to destroy the enzymes present. The saliva was then centrifuged at 3000 revolutions per minute (rpm) for fifteen minutes. The supernatant was separated and diluted in a 1: 4 ratio. All the saliva samples were tested for secretor status on the same day of their collection.

**c) Dilution of Anti-Serum**
Anti-A and Anti-B antisera were used for patients of Blood Group A and Blood Group B and Anti-H antisera was used for patients belonging to Blood Group O. Antisera were diluted in a dilution of 1: 8. E.g. if diluted anti-A was to be prepared, four test tubes were kept in a row and one drop of saliva was put into each tube. One drop of Anti-A was now added to the first tube and mixed. Then one drop of diluted serum was taken from the first tube and added to the second tube. The same procedure was followed up to the fourth tube. (Ref) as shown in the table below:

<td>1:8</td>
</tr>
</tbody>
</table>

One drop of processed saliva and one drop of diluted anti-serum from test tube four (1: 8 dilution) were now added to fresh test tube.

**d) Procedure to determine Secretor Status**
The contents were mixed well and allowed to stand for fifteen minutes. Then a drop of standard red cell suspension was added and allowed to stand for sixty minutes. The mixed solution was examined under microscope. Care was taken to wash the pipette repeatedly, immediately after each dip. No agglutination suggested the presence of antigen in saliva, while agglutination suggested the absence of antigens in the saliva. Saline controls were kept simultaneously with the test.

**RESULTS**
The study was done to find out that there is any correlation between ABO blood groups, secretor status and the incidence of IHD in Kadapa district. 600 IHD patients (444 males and 156 females) and 600 control (412 males and 188 females) subjects participated in the study.

A total of 129 (21.5%) IHD patients and 476 (79.4%) control subjects were secretors, while 471 (78.5%) IHD patients and 124 (20.6%) control subjects were non-secretors.

DISCUSSION

The frequency of ABH secretors and non-secretors in the control subjects were 79.4% (476) and 20.6% (124) respectively. Whereas, the frequencies of secretors and non-secretors in the IHD patients were 21.5% and 78.5% respectively. The frequency of ABH secretor status in the control subjects in this study is generally higher than what is obtainable worldwide, where about 20.6% are non-secretors. Igbeneghu et al(10) reported a frequency of 75% secretors and 25% non-secretors in Osogbo in south-western Nigeria, while Jaff(12) reported a frequency of 76% secretors and 24% non-secretors in Iraq. Akhter et al(13) found a frequency of ABH secretor status of 60% and non-secretors of 40% in Dhakar.

The FUT2 gene encodes fucosyltransferases that transfer a terminal fucose residue to a pre-existing precursor substance to form a soluble H antigen in secretory tissues, which serves as a precursor for soluble ABH antigens. Hence, individuals having at least one functional FUT2 allele, their ABH antigens are not only detected on their cell surfaces, but also in their body fluids including saliva. Non-secretors are homozygous for two inactive FUT2 alleles (SeSe). It is therefore possible that the presence of genes that predispose a person to IHD may down-regulate the expression of FUT2 (secretor) gene and secrete enzymes, leading to the higher percentage of non-secretors in IHD patients.

CONCLUSION

The study concludes that there is a significant correlation between ABO blood types and secretor status. The incidence of IHD is more common in B group non-secretors in Kadapa city. This is in correlation with study done by Meian He et al(15) that non-O blood group had higher risk of Coronary Heart Disease (CHD),(16,17,18,19) because factor VIII-vWF levels are a risk for CHD.(20,21) IHD was associated with ‘A’ blood group in studies of Saima Sharif et al(22) and was associated with ‘B’ group in studies of Shazia Chowdhary et al.(23)

Recommendations

To reduce the risk, lifestyle modifications like physical exercise, antioxidant rich diet like fruits, vegetables and polyunsaturated fats contained at an early age by reducing the role of risk factors for ischaemic heart disease as secretor status and ABO types are genetically determined.(24)
