ABSTRACT

BACKGROUND
Pterygium, a growth of fibrovascular tissue on the cornea, which appears to be continuous with conjunctiva. Its treatment is mainly surgical.

AIMS AND OBJECTIVES
To compare three surgical techniques in management of pterygium.

STUDY DESIGN
Prospective randomised interventional study.

MATERIALS AND METHODS
The study was conducted from November 2013 to November 2015 at the Department of Ophthalmology, GMC, Haldwani, Uttarakhand. All the patients of primary nasal pterygium who came in OPD were selected for surgical intervention. A total number of 75 eyes (75 patients) undergoing pterygium excision with conjunctival autograft were taken and randomly allocated to three groups: Autograft using autologous blood (Group A, 23 patients), Autograft using fibrin glue (Group F, 21 patients) and Autograft using sutures (Group S, 31 patients). The three groups were compared for: duration of surgery, postoperative discomfort and complications.

RESULTS
The duration of surgery was longer in group A (23.73± 1.05 min.) and S (25.51± 3.01 min.) as compared to group F (20.22±0.8 min). In Group S, 15 patients (48.38%) reported moderate postoperative discomfort on day 1 and also for the longest duration. Graft oedema was comparable in the three groups. Graft displacement was seen in 1 patient of group A (4.34%).

CONCLUSION
Three surgical techniques used in study are equally effective, but have their own merits and demerits. Postoperative discomfort and suture related complication remains a drawback in suture group. Fibrin glue possesses less complication, but affordability is an issue. Autologous blood is cost effective, has less postoperative discomfort, but graft displacement remains a concern.

KEYWORDS
Pterygium Management, Surgical Technique, Comparative Study.

INTRODUCTION
Pterygium is a degenerative condition of subconjunctival tissue which proliferates as vascularised granulation tissue to invade the cornea, damaging the superficial layers of stroma and Bowman’s membrane, may encroach upon pupillary area. As a result of tissue fibrosis, it may lead to alteration of corneal curvature leading to astigmatism and corneal opacity. Its prevalence rate varies from 0.3% to 29% in various parts of the world.¹

Medical treatment of symptomatic patients involves tear substitutes, and topical steroids, and sunglasses (to reduce UV exposure).² Pterygia warrant surgical treatment when they cause discomfort (Not responsive to conservative therapy), encroach upon the visual axis, induce significant astigmatism, or become cosmetically bothersome. A variety of surgical techniques have been developed.

Recurrence rate is very high after simple excision (Bare sclera), main challenge is prevention of its recurrence.³ The 50% reoccur within 4 months of excision and nearly all within 1 year.⁴ Beta-radiation applied postoperatively to the pterygium base was popular for many years, but is associated with late scleral necrosis.⁵ Currently, the most widely used techniques are conjunctival autografting, amniotic membrane transplantation, and mitomycin-C application – either pre, intra, or postoperatively.⁵,⁶ Fibrin-based glues have been used...
to minimise operating time and discomfort associated with sutures and to reduce the amount of suturing required.

In recent past, the debate over best approach to surgery was centred on sutures and fibrin glue to affix the conjunctival graft. Former requires good surgical skill and is associated with high postoperative suture related discomfort. Biodegradable nature of glue leads to less inflammation, but its high cost, risk of transmission of prion disease and anaphylaxis are its are main limiting factors.

The technique of using patient’s own blood (autologous blood) to fix graft to recipient site reduces the operating time, suture related postoperative complications, overcomes complications of glue and reduces the economic burden.

**AIMS AND OBJECTIVES**
1. To compare duration of surgery in three groups.
2. To compare postoperative discomfort in three groups.
3. To compare the postoperative complications in three groups.

**MATERIALS AND METHODS**

The study was conducted at the Department of Ophthalmology, Government Medical College, Haldwani-Nainital, Uttarakhand. It was a prospective, randomised, interventional study during a period of 2 years from November 2013 to November 2015.

A total number of 75 eyes (of 75 patients) presenting to the outpatient department (OPD) needing surgical intervention were selected. Informed written consent was taken from the patients before performing the surgery. Patients were randomly allocated to three groups: Group A: autograft using autologous blood (23 patients); Group F: autograft using fibrin glue (21 patients); Group S: autograft using sutures (31 patients).

**Inclusion Criteria**
1. Encroachment upon visual axis.
2. Significant decrease in visual acuity due to astigmatism.
3. Causing recurrent irritation.
4. Cosmetically bothersome to the patient.
5. Patients older than 20 years and younger than 60 years.

**Exclusion Criteria**
1. Temporal pterygium.
2. Recurrent pterygium, Atrophic pterygium.
3. Pseudopterygium.
4. Patients on anticoagulants.
5. Patients with pre-existing glaucoma.
6. History of previous ocular surgery or trauma.

After surgical intervention, eyes were patched for 24 hours in Group S and Group F and for 48 hours in Group A.

Postoperatively, topical antibiotics, steroids and lubricants were given. Followup visits were done on 1st week, 1, 3 and 6 months.

The three groups were compared for: duration of surgery, postoperative discomfort and complications. The complications included recurrence, graft oedema, graft stability and suture related complications like granuloma formation, suture abscess, pyogenic granuloma.

Mean duration of surgery was noted in the three groups and it was calculated from the time putting the traction suture to the removal of lid speculum.

Postoperative discomfort was graded on visual analogue scale (VAS) as mild (1-3 score on numeric VAS scale), moderate (4-6 score on numeric VAS scale), and severe (7-10 score on numeric VAS scale).

Graft stability was assessed on day 1 in Group S and Group F and day 2 in Group A.

**RESULTS AND OBSERVATIONS**

A total number of 75 eyes (of 75 patients) presenting to the outpatient department (OPD) needing surgical intervention were selected. Patients were randomly allocated to three groups: Group A: autograft using autologous blood (23 patients), Group F: autograft using fibrin glue (21 patients), Group S: autograft using sutures (31 patients).

Out of the 75 patients, 29 were males and 46 females showing a female predilection (Table 1).

*Table 2: Distribution according to Occupation*
On 1st postoperative day, as many as 15 (48.38%) patients in group S reported moderate discomfort, whereas only mild discomfort was reported by 16 (69.56%) patients in group A and by 12 (57.14%) in group F (Table 3.1, 3.2 and 3.3).

Most of patients in all groups did not report any discomfort beyond 1st week of followup. Severe and moderate discomfort was not reported in any group beyond 1st week of followup.

In group A and F, no patient reported discomfort after 1-month duration, but 2 (6.46%) patients in group S reported mild discomfort as long as 3 months.

At 6 months followup, no patient reported any discomfort.

**DISCUSSION**

Many previous studies suggest that the prevalence of pterygium is higher in males (Hilgers JH et al). But in present study, we have seen a higher prevalence of pterygium in
females (61.34%). Reason for higher prevalence could be greater UV light and dust exposure due to outdoor work of women in hilly region of Kumaon to earn livelihood.

Study by Lu P et al\(^1\) reported a higher prevalence of pterygium in female than male, which he suggested could be due to Tibetan lifestyle where women had mainly rural and outdoor work. Most of patients in the present study were from middle age group, (mean age in group A being 36.5 years; in group S, 41.97 years; in group F, 32.76 years).

In present study, most of the patients were field workers/labourers (57.34%). Mackenzie FD et al reported that there are 4 to 11 times more chances of having pterygium in persons working outdoors, exposed to sun and dust.\(^10\)

Management of pterygium remains challenging. Medical treatment in the form of topical NSAIDS, steroids, lubricants and injection of anti-VEGF agents have limited role. Till date, surgical management remains treatment of choice. But there are problems with surgical treatment also. Bare sclera left behind after simple excision of pterygium is associated with recurrence rates of 30% to 70%. With adjunctive measures such as topical Thiotepa, 5-fluourouracil, or mitomycin-C the recurrence rate is lower but there is a high risk of complications with these agents.

 Conjunctival autografting after pterygium excision is associated with lower recurrence rates (2% to 9%) and relatively few sight threatening complications.\(^11,12\)

Different methods of securing graft to scleral bed are in practice now. But securing the graft with sutures is the most commonly performed procedure. Korany and associates\(^12\) were the first to report the use of fibrin glue. Risk of transmission of prion disease and risk of anaphylaxis in susceptible individuals\(^8\) are main limiting factors in glue method of treatment.

In the present study, we have compared the three methods of surgical management in view of postoperative discomfort. On 1\(^{st}\) postoperative day, as many as 15 (48.38%) patients in group S reported moderate discomfort, whereas only mild discomfort was reported by 16 (69.56%) patients in group A and by 12 (57.14%) in group F. Most of the patients in all 3 groups did not report discomfort beyond 1st week of followup.

Several other studies also reveal similar discomfort in postoperative period. (SAM Elwan et al, P Peusch et al\(^1\), D de Wit et al\(^1\)).

Graft displacement is a major concern in grafts fixed by autologous blood in immediate postoperative period and most of them occur within 24 to 48 hours of surgery. Graft usually dislocates due to undue rubbing of operated eye due to foreign body sensation, which can be prevented by proper counselling. Graft retraction at its bed is also an issue with this technique, but appropriately thin graft of adequate size avoids this complication in most of the patients. In present study, graft was displaced in 1 patient (4.34%) and patient gave the history of rubbing the eye. Nisha Dulani et al also reported graft displacement in only 3.39% of the patients.

Graft oedema occurred in comparable ratio in group A and S i.e. 43.47%, 45.16%, but it was comparatively less i.e. 38.09% in group F. This reduced after giving topical steroids in tapering doses. In study of Cevala Markovskaat a\(^1\) graft oedema was present in 22.5% of cases in Suture group. In our study this is greater. Type of pterygium and intraoperative manipulation may be responsible for greater graft oedema.

At the end of 6 months, recurrence was seen in 1 patient in each of the 3 groups i.e. 4.34% in group A, 3.22% in group S and 4.76% in group F. Similar studies by Malik KPS et al\(^13\) and Nisha Dulani et al also correlate with recurrence rates of present study.

Mean duration of surgery in Group A was 23.73±1.05 minutes while in group S it was 25.51±3.01 minutes. The mean duration was less in group F (20.22±0.8 minutes) as compared to the other groups. In a study by SAM Elwan et al\(^15\), mean operating time was 24 minutes in Autologous blood group and 28.64 minutes in Suture group which correlates with present study.

CONCLUSION

Postoperative discomfort and suture related complications remain the drawback in suture group. The technique for graft fixation using fibrin glue poses less complications, but affordability is an issue in our patients, who are mainly field workers and labourers. Fibrin glue being costly is not affordable by most of the patients in our region.

Graft fixation using autologous blood is cost effective, has less postoperative discomfort and no risk of viral disease transmission, but graft displacement remains a concern of this technique, though the overall incidence of this complication is very less.

The fact is that numerous surgical techniques exist for the surgical treatment, but the point is that no approach is universally successful.
