ABSTRACT

BACKGROUND
Acute Myocardial Infarction (AMI) is the leading cause of mortality in both developed and developing countries.1,2 Acute coronary syndromes are emerging out in epidemic proportions throughout the world. Factors contributing to death following acute myocardial infarction are many.

Aims- To assess the prognostic significance of serum uric acid level in acute myocardial infarction and to assess the prognostic significance of serum uric acid levels with incidence of cardiac failure.

MATERIALS AND METHODS
This study was conducted in the Department of Medicine and Department of Cardiology, Mahatma Gandhi Memorial Hospital/Kalatya Medical College, Warangal during the period from February 2013 to August 2014. Total number of patients included in this study were 100. There were 77 males, 23 female patients, age ranging from 42 years to 72 years.

RESULTS
The study population consisted of 100 patients with 77 males and 23 females. All patients belonged to places around Warangal District. All patients were admitted in Intensive Cardiac Care Unit initially for 5 days, then cared in adjoining intermediate cardiac care ward and discharged after an average period of 7 days provided there were no complications.

Total number of patients included in this study was 100, out of which 47 patients had elevated levels of uric acid above normal range and 53 patients had normal serum uric acid levels following acute myocardial infarction.

CONCLUSION
There is a significant association between elevated SUA and cardiac failure. Patients with high SUA level belonged to higher Killip class (III & IV). Elevated uric acid level had an objective correlation with echocardiographic evaluation of LV dysfunction.

KEYWORDS
Uric acid, Prognosis, Mortality.

Hence, many trials have been conducted to identify markers that would be helpful to predict the risk of such adverse cardiac events.

Many trials have used serum Magnesium level,1 C-reactive protein levels,2 malonyldialdehyde,3 white blood cell count4 as a predictor for mortality and morbidity following acute myocardial infarction and risk of developing adverse cardiac events like sudden cardiac death and congestive heart failure.

Previous studies have established that Serum Uric Acid (SUA) levels reflect circulating xanthine oxidase activity and oxidative stress production following acute myocardial infarction.

Free radicals produced in large amounts during myocardial ischaemia and reperfusion, take part in the degradation of cellular and subcellular membrane structures. The source of oxygen radicals in ischaemic myocardium are neutrophils recruited into the necrotic region as well as metabolic transformation of Hypoxanthine and Xanthine to Uric acid.5

Thus, it is evident that elevated Uric Acid (UA) levels is a good marker of oxidative stress and useful to assess the prognostic events in acute myocardial infarction.

This forms the basis of the study.

Financial or Other, Competing Interest: None.

ABSTRACT

BACKGROUND
Acute Myocardial Infarction (AMI) is the leading cause of mortality in both developed and developing countries.1,2 Acute coronary syndromes are emerging out in epidemic proportions throughout the world. Factors contributing to death following acute myocardial infarction are many.

These factors relate mainly to electrical disturbances in the form of arrhythmia3 and mechanical disturbances in the form of pump failure.4,5

Most sudden deaths in acute myocardial infarction occur within one hour due to ventricular fibrillation and also due to left ventricular failure when there is an extensive injury.6 Rest of the deaths following myocardial infarction occur within first one week and death cannot be predicted and occurs suddenly.
AIMS OF THE STUDY
1. To assess the prognostic significance of serum uric acid level in acute myocardial infarction.
2. To assess the prognostic significance of serum uric acid levels with incidence of cardiac failure.
3. To validate the prognostic significance between quantitative serum uric acid level on admission and high Killip's class status in acute myocardial infarction.
4. To assess the prognostic significance of serum uric acid levels with incidence of short-term mortality.

MATERIALS AND METHODS

Study Population
This study was conducted in the Department of Medicine and Department of Cardiology, Mahatma Gandhi Memorial Hospital/Kalatya Medical College, Warangal during the period from February 2013 to August 2014. Total number of patients included in this study were 100. There were 77 males, 23 female patients, age ranging from 42 years to 72 years.

Study Design
This study is a prospective study. This study is aimed to assess the prognostic role of serum uric acid level following acute myocardial infarction and correlating the levels with short-term complications.

This study included 100 patients of acute myocardial infarction of which patients who had a normal uric acid level were taken as a population with normal serum uric acid and the rest who had elevated uric acid level were taken up as a population with hyperuricaemia.

In both groups, the complications and short-term outcome were compared.

Inclusion Criteria
Patients with a diagnosis of acute ST Elevation Myocardial Infarction were entered into the study. A definite diagnosis of acute ST Elevation Myocardial Infarction was made if the patients satisfied the following criteria: A history of typical retrosternal compressive chest pain lasting for more than 30 minutes, not relieved by rest or nitrates. Typical ECG changes of acute ST Elevation Myocardial Infarction.

Exclusion Criteria
Patients with elevated renal parameters, Patients with Gout, Patients with history of chronic alcoholism, Patients with previous history of Ischaemic Heart Disease, Patients with diabetes mellitus, Patients on diuretic & aspirin therapy. Above patients were excluded because the coexisting disease or drug therapy might itself produce a high uric acid level.

Very late presentations of patients more than 72 hours also excluded since uric acid level tends to fall subsequently (Journal of the Indian Medical Association 1977 Sep. 1).

Variables Recorded During the Study
History, physical examination, routine laboratory investigations were performed in all subjects.

1. Presenting History
   - Duration of chest discomfort.
   - Associated symptoms like sweating, palpitations, breathlessness.
   - Time of onset of symptoms.

2. Admission Electrocardiogram (ECG).
5. 2D echo cardiogram (left ventricular ejection fraction (LVEF)).
   - Complete blood picture.
   - Random blood sugar, Serum lipid profile.
   - Blood urea, Serum creatinine, Serum electrolytes.
   - Serum uric acid level on admission.
   - Urine albumin, sugar, deposits.

Qualifying patients received thrombolytic therapy with 1.5 million units of streptokinase followed by heparin for 5–7 days.

Assessment of left ventricular ejection fraction by echocardiography was performed either on day 4 or 5 of hospitalisation in most patients or earlier if clinically indicated.

Uric Acid Estimation
Immediately after admission, blood sample of 3 cc was drawn by venepuncture and transferred to dry plain bottle and taken to biochemistry laboratory.

The method used for analysis is enzymatic method (Uricase method) by using autoanalyser.

In our laboratory, values taken as normal range.

Methodology
Methods using uricase, the enzyme that catalyses the oxidation of uric acid to allantoin are most specific. The simplest of these methods measures the differential absorption of uric acid and allantoin at 293 nm. The difference in absorbance before and after incubation with uricase is proportional to the uric acid concentration. This method has been proposed as candidate reference method.

This method was done in our study. This is the most specific method.

Followup
All the patients were followed up for a period of 7 days. During followup, any changes in Killip’s classification, features of cardiac failure and any mortality were noted in both groups of patients. Routine daily physical examination was done. ECGs were taken daily and additional investigations carried out if necessary. Patients were discharged on 8th day if they were stable, otherwise their hospital stay was prolonged.

Framingham criteria for heart failure like JVP elevation, basal rales, acute pulmonary oedema, S3 gallop, tachycardia (>100/min.), lower extremity oedema were used in this study for making a diagnosis of CCF.

OBSERVATIONS AND RESULTS
The study population consisted of 100 patients with 77 males and 23 females. All patients belonged to places around Warangal District. All patients were admitted in Intensive Care Unit initially for 5 days, then cared in adjoining intermediate cardiac care ward and discharged after an average period of 7 days provided there were no complications.
The various observations made in this study are depicted below.

### Table 15: Proportion of Arrhythmias Contributed by Patients with High and Normal Serum Uric Acid Level

i.e. 36% of patients with hyperuricaemia and 15% of patients with normouricaemia had LVEF<50%.

i.e, 7% of patients in this study developed arrhythmias.
Contribution of patients with high serum uric acid level to arrhythmias: 71% Contribution of patients with normal serum uric acid levels to arrhythmias: 29%.

It is observed that patients with high SUA level contribute 71% to the total incidence of mortality

Incidence (5×100÷53)=6%

i.e. 6% patients with normal uric acid level died in the study.

**DISCUSSION**

Total number of patients included in this study was 100, out of which 47 patients had elevated levels of uric acid above normal range and 53 patients had normal serum uric acid levels following acute myocardial infarction.

The significance level between two parameters is assessed by applying Chi-square test.

**Age**

Out of the 100 patients, 10 patients were in the age group of 31-40 years, 22 patients were in the age group of 41-50 years, 37 patients were in the age group of 51-60 years, 24 patients were in the age group of 61-70 years, 7 patients were in the age group of 71-80 years. (Table 1).

**The Results of Other Studies as Follows**

<table>
<thead>
<tr>
<th>Age in Years</th>
<th>High Uric Acid</th>
<th>Normal Uric Acid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Present Study</td>
<td>59.55</td>
<td>58.16</td>
</tr>
<tr>
<td>Agarwal S et al</td>
<td>60.59</td>
<td>58.90</td>
</tr>
</tbody>
</table>

The mean ages in hyperuricaemic population and in normouricaemic population were 59.55 years, 58.16 years respectively in this study.

Present study results are comparable with Agarwal S et al study.

**Sex Ratio (Table 2)**

In this study, male and female ratios were 3.34:1, 2.12:1 and 4.2:1 in total population, hyperuricaemic population and normouricaemic population respectively.

<table>
<thead>
<tr>

<tr>
<td>MY Nadkar et al</td>
<td>1.7 : 1</td>
<td>3.54 : 1</td>
</tr>
</tbody>
</table>

Present study correlates with MY Nadkar et al study.

**Population with Hyperuricaemia & Population with Normouricaemia**

Out of 100 patients studied, 53 patients had normal uric acid level and they were taken up as patients with normal serum uric acid. Of which 43 (81%) were males and 10 (19%) were females. The rest 47 patients had elevated serum uric acid level and they were taken up as patients with hyperuricaemia. Of which 34 (72.3%) were males and 13 (27.7%) were females.

Both were compared with various outcomes.
In this study, the mean serum uric acid levels in males & females were 6.25 mg/dL & 5.98 mg/dL respectively. The mean serum uric acid levels in patients with high serum uric acid and in patients with normal uric acid were 7.48 mg/dL & 4.94 mg/dL respectively. The mean serum uric acid in Shirisha Agarwal et al was 7.03 mg/dL, 5.77 mg/dL in hyperuricaemia and normouricaemia population respectively. So present study correlates with this study.

Clinical Status-Killip Class & Serum Uric Acid
In this study, 23 patients presented with Killip class I, 36 patients presented with Killip class II, 18 patients presented with Killip class III, 23 patients presented with Killip class IV. Killip class II & IV were taken as high risk category in this study and evaluated whether high uric acid concentration after myocardial infarction correlated with this high risk Killip class.

When clinical status of patients based on Killip class I to IV and uric acid were analysed, the following observations were made. In the patients with normal serum uric acid level, 75% belonged to I & II Killip class and only 25% belonged to Killip class III & IV whereas in patients with hyperuricaemia, 40% belonged to Killip class I & II and 60% belonged to Killip class III & IV (Table 5 & 6).

The results of this study showed significant association between high serum uric acid levels and higher Killip class (III & IV) of heart failure (p <0.05).

Shoha Shetty et al15 showed that in patients with higher Killip class (II & IV), there were high serum uric acid levels (p <0.001).

MY Nadkar, VI Jain et al also found similar results between high serum uric acid levels and higher Killip class (III & IV).

Echocardiogram
In high uric acid population, 17 (36%) patients had LVEF <50% and 30 (64%) patients had LVEF >50% whereas in normal uric acid level population, 8 patients had LVEF <50% and 45 patients had LVEF >50% (Table 12).

Among 17 hyperuricaemia patients, 16 (95%) are males and 9 (53%) are females. Patients who had elevated serum uric acid level, hyperuricaemia is significantly associated with LVEF <50% (p <0.05).

Results of other studies are as follows

<table>
<thead>
<tr>
<th></th>
<th>High SUA</th>
<th>Normal SUA</th>
<th>P* value</th>
</tr>
</thead>
<tbody>
<tr>

<td>15.1%</td>
<td>&lt;0.05</td>
</tr>
</tbody>
</table>

*Chi-square test

Present study results are similar to results of reference study. So uric acid level can be used as a definite predictor of cardiac failure.

Arrhythmias
7 out of 100 patients developed arrhythmias in this study. So the incidence of arrhythmias was 7% of which 6 (86%) were males, 1 (14%) was female. 3 patients had ventricular tachycardia and 4 patients had supraventricular tachycardia (Table 13 & 14).

It was observed that among 7 arrhythmias, 5 patients had high uric acid level and 2 patients had normal uric acid level. So patients who had high uric acid level and normal uric acid level contributed to 71% and 29% respectively to arrhythmias (Table 15).

It was also found that 5 patients out of 47 patients with high uric acid level had arrhythmias amounting to an incidence of 11% arrhythmias in this group while only 2 out of 53 patients with normal uric acid level had arrhythmias i.e. only 4 % of patients with normal uric acid level had arrhythmias. (Table 16 & 17).

The above findings suggest that the occurrence of arrhythmias is also high in patients with high uric acid level. But hyperuricaemia was not significantly associated with development of arrhythmias in this study (p = 0.17939(NS)).

Results of other studies are shown below.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

*chi-square test

This observation can be matched with the outcome of a large randomised double blind placebo control clinical trial “Oxypurinol therapy for CHF” conducted in 2003, which could establish a beneficial effect for oxypurinol in reducing the incidence of arrhythmias and other adverse cardiac events by lowering serum uric acid level.

The above studies & present study tells there is a high incidence of arrhythmias when there is an elevated serum uric acid level and it is hypothetical an increased uric acid level may be arrhythmogenic. Further studies are needed to conclude it.

MORTALITY
15 out of 100 patients died due to their cardiac ailments in this study. This amounts to mortality rate of 1.5% of which 14 (93%) were males, 1 (7%) was female. (Table 18 & 20).

Out of 15 deaths, 3 patients (20%) were in the age group of 41-50 years, 6 patients (40%) were in the age group of 51-60 years, 4 patients (27%) were in the age group of 61-70 years, 2 patients (13%) were in the age group of 71-80 years (Table 19).

To find out the prognostic significance of elevated uric acid level following acute myocardial infarction, mortality rate in patients with normal and high uric acid level were separately calculated.

It was observed that among 15 deaths, 12 deaths were contributed by patients with high uric acid levels and 3 deaths by those who had normal uric acid levels. Thus, 80% of deaths in post-infarction period occurred in those who had a high uric acid level and only 20% in those who had a normal uric acid level (Table 21).

It was also found that 12 out of 47 patients with high uric acid level died. This implies a mortality rate of 26% in patients with hyperuricaemia.

Likewise a mortality rate of 6% was observed for patients with normal uric acid level following myocardial infarction (Table 22 & 23).

<table>

</tbody>
</table>

*chi-square test

This striking difference in the mortality figures for both group of patients implies uric acid level can be used as a predictor of mortality following myocardial infarction. The association between hyperuricaemia and mortality was found to be significant (p < 0.05).

CONCLUSION
1. There is a significant association between elevated SUA and cardiac failure.
2. Patients with high SUA level belonged to higher Killip class (III & IV).
3. Elevated uric acid level had an objective correlation with echocardiographic evaluation of LV dysfunction.
4. Elevated serum uric acid level may be arrhythmogenic. Further studies are needed to confirm it.
5. A high serum uric acid level correlated with short-term mortality in acute myocardial infarction.
6. Measuring serum uric acid level is one of the predictable prognostic indicator in acute myocardial infarction and one of the early and short-term predictor.

Till date several studies have evaluated the predictive value of on admission serum uric acid and its outcomes in AMI; it has been shown to have an adverse effect in short and long term in patients with AMI. There are many developed countries that are using pharmacological approach for their AMI system of care (Fibrinolytic treatment in pre-hospital setting with an invasive procedure backup), but in developing countries like India, serum uric acid is an economical biomarker that is readily, quickly and reliably obtainable and thus, along with Killip’s classification, should be incorporated for risk stratification in patients with AMI.
