4Professor and HOD, Department of Ophthalmology, Government Medical College, Srinagar.

ABSTRACT

BACKGROUND
Ocular trauma is a major cause of visual impairment throughout the world, although little is known about its visual outcome in developing countries.

AIMS AND OBJECTIVES
To assess the visual outcomes and post-operative complications following the management of traumatic cataracts.

MATERIAL AND METHODS
This prospective hospital-based study was conducted on 40 patients of traumatic cataract. Patients were managed with lens extraction and intraocular lens implantation. Regular follow-up of patients was done and best corrected visual acuity and post-operative complications were assessed at the end of six months.

RESULTS
Our study showed that majority (50%) of patients were in the age group of <20 years with male preponderance; 37 cases (92.5%) were successfully rehabilitated with IOL implantation as primary or secondary procedure. Out of 40 cases, BCVA of 6/18 - 6/6 was recorded in 28 cases (70%), 6/36 - 6/24 in 8 cases (20%) and had BCVA of equal to or less than 6/60 in 10 cases. Most common complications reported were anterior chamber reaction and Posterior Capsular Opacification (PCO).

CONCLUSIONS
92.5% patients were safely rehabilitated with cataract extraction and IOL implantation and 70% had BCVA of 6/18 - 6/6. Posterior capsular opacification and uveitis were the common post-operative complications.

KEYWORDS
Traumatic Cataract, Visual Outcome, Best Corrected Visual Acuity, Ocular Trauma.

INTRODUCTION
Ocular trauma is a major cause of monocular blindness and visual impairment throughout the world, although little is known about its epidemiology or associated visual outcome in developing countries.[1] Traumatic cataract is a very common sequel of ocular trauma.[2] It may occur when natural lens is damaged either by a blunt or penetrating injury. The methods used to evaluate the visual outcome in eyes managed for traumatic cataracts and senile cataracts are similar.[3] but the damage to other ocular tissues due to trauma may compromise the visual gain in eyes operated on for traumatic cataracts. Post-operative inflammation is a common complication following traumatic cataracts, hampering visual outcome.[4,5,6,7] Other complications leading to decreased post-operative vision are corneal scar, uveitis, secondary glaucoma, pupillary capture, posterior capsular opacification and retinal scar.[4] The aim of this study was to assess the visual outcomes and post-operative complications following the management of traumatic cataracts.

AIMS AND OBJECTIVES
The aim of this study was to assess the visual outcomes and post-operative complications following the management of traumatic cataracts.

MATERIAL AND METHODS
This prospective study was carried out in the upgraded Department of Ophthalmology Government Medical College, Jammu, from 1st July 2011 to 31st October 2012. A comprehensive proforma was designed for this study. The study was conducted on patients of traumatic cataract as a result of ocular injury from blunt or penetrating trauma admitted in the department. Patients who gave consent and were cooperative and willing for the surgery were included. Personal information of all the patients was recorded. After admission to the hospital, detailed history was taken with particular reference to age, sex and mode of injury, causes and activity at the time of injury. Preoperative assessment included: Best Corrected Visual Acuity (BCVA) by Snellen test-type, extraocular movements, fixation preferences, pupillary reflexes, slit lamp biomicroscopy of the anterior segment, applanation tonometry, dilated refraction, fundus examination with indirect opthalmoscope, keratometry (Opposite normal eye was used in case of corneal surface irregularities), intraocular lens power calculation and B-scan was done. Other relevant examinations and routine investigations were also done as well before surgery. Corneal laceration more than 10 mm, injuries like iridodialysis, zonular dehiscence, vitreous...
haemorrhage, retinal detachment, cases with age less than two years were excluded from the study.

All cases were subjected to surgery under local or general anaesthesia. The standard surgical procedure performed was SICS with posterior chamber IOL implantation, primary lens aspiration at the time of wound repair with primary or secondary IOL implantation. These surgical procedures were combined with other surgical procedures depending upon the need in individual cases. Post-operatively, all patients were treated with topical steroids along with topical antibiotics and non-steroidal anti-inflammatory drugs. Steroids were gradually tapered over next six weeks to two months. Patients were discharged with topical antibiotics, steroids and topical cycloplegics. Patients were called for regular follow-up after three days, then once a week for next six weeks, monthly for next three months and thereafter every three months. On follow-up visual acuity, IOP recording, detailed slit lamp biomicroscopy to rule out any uveitis, intraocular lens decentration, synchia, pupillary capture and posterior capsular opacification were done. Posterior segment evaluation was done with indirect ophthalmoscopy.

This study was in accordance with the ethical standards of Declaration of Helsinki and was approved by the Ethical Committee of the Institution. A written informed consent was taken from all the participants. Forty cases that were admitted in our institution were studied over a period of one and a half year from July 2011 to October 2012.

RESULTS
In this study, 50% cases were found in the age group of 5-20 years followed by 32.5% in age group 21-40 years. The male:female ratio is 3:1.

Majority of patients (62.5%) had traumatic cataract due to penetrating trauma and 37.5% due to blunt trauma. Causative agents of trauma include wooden particles like stick, thorn and bow arrow in 24 cases (60%), metallic agents like iron rod, wire, compass in 4 cases (10%), stone in 2 cases (5%) and with glass piece in 4 cases (10%).

The morphology of traumatic cataract was total in 27 cases (67.5%), soft cataract with ruptured anterior capsule in 6 cases (24%) and membranous and rosette cataract in 2 cases (8%) each. Table 1 shows Best Corrected Visual Acuity (BCVA) at the time of presentation.

The interval between trauma and surgery was less than three months in 24 cases (60%), 4-6 months in 7 cases (17.5%), 7-12 months in 3 cases (7.5%), 13-18 months in 2 cases (5%) and more than 18 months in 4 cases (10%).

Out of 40 cases, 37 cases (92.5%) were successfully rehabilitated with IOL implantation as primary or secondary procedure; 30 cases underwent cataract extraction (SICS) with PCIOL; 9 cases presented with anterior capsular defect with presence of lens matter in anterior chamber. Among these, 4 cases underwent primary lens aspiration with primary IOL implantation and 3 cases had undergone only lens aspiration at the primary sitting with subsequent secondary IOL implantation at a later date. Three cases (7.5%) remained aphakic. Figure 1 summarises type of IOL implantation in the study patients.

A number of intraoperative and postoperative (early and late) complications were noted. Vitreous loss was seen in 3 (7.5%) cases and hyphema in 2 (5%) cases. Postoperative complications noted are shown in Table 2.

In patients with significant posterior capsule opacification, Nd-YAG laser capsulotomy was done in 7 (17.5%) and membranectomy in 1 (2.5%).

Final BCVA was assessed at the end of 6 months. Out of 40 cases, BCVA of 6/18 - 6/6 was recorded in 28 cases (70%). BCVA of 6/36 - 6/24 was seen in 8 cases (20%); 10 cases had BCVA equal to or less than 6/60 as shown in Table 3.

DISCUSSION
The present study brought within its preview 40 patients of traumatic cataract admitted in Department of Ophthalmology, Govt. Medical College, Jammu, from July 2011 to October 2012. Injury to the eye represents a major threat to vision and this may happen to any individual at any age in any work place. Ocular trauma often leads to traumatic cataract along with damage to other ocular structures. Traumatic cataract was managed with lens extraction and intraocular lens implantation. Regular follow-up of patients was done and visual outcome was assessed at the end of six months. In the present study demographic, aetiological factors, type of trauma, pre-operative visual acuity, type of surgery, post-operative best corrected visual acuity and complications were assessed and analysed.

Our study showed that majority (50%) of patients were in the age group of <20 years followed by 32.5% in the age group of 21-40 years, almost similar to the results of some other studies.[9,10] while Panda A et al have reported maximum patients (31.25%) in the age group of 25-34 years.[11] In the present study, we found male preponderance of 3:1, as shown by most of the other studies.[4,9,11-13] In our study blunt trauma accounts for traumatic cataract in 37.5% and penetrating trauma in 62.5% of cases. Our results were consistent with the results obtained by Memon MN et al that penetrating trauma accounts for traumatic cataract in 68.3%.[13] Synder A et al observed penetrating trauma in 78.6% of cases,[12] and Staffieri SE et al observed 88% cases of traumatic cataract due to penetrating trauma.[14] While Gogate P et al observed traumatic cataract in 48.8% of cases due to blunt trauma and 39% of cases due to sharp trauma.[15]

In our study wooden material like stick, thorn was the major cause of traumatic cataract which matches closely with study of Memon MN et al[13] and Shah MA.[14] In our study, 67.5% had total cataract which matches with study of Panda A et al, which had 74% total cataract.[11] In our study soft cataract was noticed in 22.5%, which is consistent with the study of Zaman M et al, which had soft cataract with ruptured anterior capsule in 25.97% of cases.[9] Shah M et al in their study showed 59.9% patients had white soft cataract with ruptured anterior capsule followed by 26.6% had total cataract.[14] In our study more than half of patients had pre-treatment best corrected visual acuity of light perception only, which is consistent with study of Ahmed N et al[15] where half of patients had visual acuity of hand movement and with study of Kumar S et al[17] where maximum patient had visual acuity of light perception only.

In the present study, time interval between trauma and cataract surgery ranges from same day to 10 years. Maximum patients (60%) presented to the hospital and underwent cataract surgery within 3 months, 17.5% patients within 4-6 months, 10% patients were operated upon after 18 months, 7.5% patients within 7-12 months followed by 5% within 13-18 months. One (2.5%) patient was operated for traumatic cataract 10 years after trauma, while Eckstein M et al in their study showed time interval between injury and cataract surgery ranged from 1-60 weeks with mean interval was 10.4 weeks.[18] In our study 92.5% patients were safely rehabilitated with IOL implantation which is consistent with the study of Panda A et al, as they put IOL in 89.2% of patients.[11] and Gogate P et al in 90.2% of patients.[15] Most common complications reported in our study were anterior chamber reaction and PCO, which is consistent with study of Memon MN et al,[13] Zaman M et al,[9] Synder et al[12], Loncar VL et al,[19] Kumar S et al.[17] Patients with uveitis were given topical corticosteroids (Prednisolone acetate 1% eye drops) and cycloplegics and they responded within six weeks. One (2.5%) patient with PCIOL in our study had intractable raised IOP; peripheral laser iridotomy was done and later on IOP remained normal. In the present study 30% had clinically significant PCO, Nd-YAG laser capsulotomy was performed in 17.5% of cases and one (2.5%) patient had very thick PCO which was resistant for Laser; in this patient surgical membranectomy was done at an interval of 4 months after surgery which matches with study of Eckstein M et al[13] in which Nd-YAG laser capsulotomy was performed in 63.46%, more than one laser session required in 11.53% and surgical membranectomy was done in 17.3%. This study revealed that satisfactory visual outcome in majority of patients with traumatic cataract can be safely achieved after cataract removal and IOL implantation and common causes of decreased vision were corneal scar, Posterior Capsular Opacification (PCO) and uveitis as was shown by other studies.[10,11,13]

SUMMARY AND CONCLUSION
Traumatic cataract resulting from ocular trauma is a common cause of ocular morbidity, especially in young population. Most of the injury occur by wooden particles like stick. Most injury occur while playing or doing domestic/agricultural work; 92.5% patients were safely rehabilitated with cataract extraction and IOL implantation and 70% had BCVA of 6/18-6/6. Posterior capsular opacification and uveitis were the common post-operative complications.
