HOW TO CITE THIS ARTICLE:

ABSTRACT: CONTEXT: Arm span is the most reliable body parameter for predicting the stature of an individual. It is useful in predicting age related loss in stature and in identifying individuals with disproportionate growth abnormalities and skeletal dysplasia. Since in Tripura variegated ethnic groups inhabit in different climatic, nutritional and ecological conditions, no single anthropometric formula is suitable. The present study was undertaken to measure the stature, as well as arm-span and to determine whether there is any correlation between the stature and the arm-span. And to estimate using respective multiplication factors the stature from arm span and to assess the effectiveness of the above estimation by comparing the 'estimated' values with the measured' values.

STUDY DESIGN: Cross sectional descriptive type of study. MATERIALS AND METHOD: The study was carried out with a total number of 100 Chakma adult female aged between 25 to 45 years. Arm-span along with their stature was measured directly from the subjects by using anthropometric technique by a measuring tape. The data were then statistically analyzed by computation to find out its normative value. Multiplication factors were estimated for estimating stature and comparison were made between measured and estimated stature using paired “t” test. RESULT: The mean normal value of the arm-span was 148.74± 5.34 cm and the stature was 149.26±5.82cm. The multiplication factor was estimated for the same hand measurements with the stature. Significant positive correlation was found in case of arm-span with the stature (r =0.89).

KEY WORDS: Anthropology, Correlation, Multiplication factor, Stature
north parts of the Tripura especially in north Tripura, Unakuti and Dhalai districts close to the Bangladesh border.

METHODS: The study was basically observational, cross-sectional and descriptive in nature. The study was carried out on 100 Chakma adult females at different locations of Unakuti and Dhalai district. To measure the stature the subject was said to stand with her heel together and her back as straight as possible so that her heels, buttocks, shoulders and the head touched the wall. The arms were hung freely by the sides with the palm facing the thighs. After asking the subject to take a deep breath and holding it, a measuring scale (steel plate) was placed against the head and wall to determine maximum height on the wall, and this was marked. The subject was then told to breathe and to step away from the wall. The height was then measured from the floor to the mark on the wall with steel tape which represents the stature in centimeters to the nearest 0.1 centimetres. Arm span was measured with a flexible steel tape from the tip of the middle finger on one hand to the tip of the middle finger on the other hand with the individual standing with her back to the wall with both arms abducted to 90. The elbows and wrists extended and the palms facing directly forward. Readings were taken to the nearest 0.1 centimeters. Each subject was measured twice. When the two measurements for each parameter agreed within 0.4 centimeters, their average was taken as the best estimate for the true value. When the two initial measures did not satisfy the 0.4 centimeters criterion, two additional determinations were made and the mean of the closest records was used as the best estimate.

Calculation of multiplication factor: Each multiplication factor is the ratio of the stature to the respective physical measurements. A mean multiplication factor was then calculated for each measurement. These mean multiplication factor were used for estimating the stature from those variables.

\[
\text{Stature} \\
M.F = \text{-----------------------------------------------} \\
\text{Upper limb variables (e.g. Arm span)}
\]

Statistical analyses of data: Results were prepared on the basis of collected data and their distribution, central tendencies and standard deviations (SD) were calculated using a computer based program (SPSS version-11.5 & MS Excel). Regression analyses were done. Mathematical relationships between sets of two measurements were calculated as multiplication factor (i.e., ratios between the two). Using the paired- t test, the measured values were compared with the corresponding values estimated (using the corresponding multiplication factor) from other relevant measurement.

RESULTS: As mentioned in Methods, measurements of stature and arm span were taken using direct physical procedure in 100 subjects. Mean and standard deviation were calculated for each variable and frequency distribution was also determined. Multiplication factor was calculated for estimating stature from each arm span measurement. Correlation of arm span with stature was also assessed. The effectiveness of the use of the multiplication factor in these estimations was tested by testing whether there are significant differences. The stature of the 100 Chakma adult female subjects
ranged from 133.00 to 162.50 centimeters, as shown in Table 1. The mean (± SD) of the stature was found 148.74 ± 5.34 cm and arm span was 149.26 ± 5.82 (Table-I). In more than 80% of the subjects, the arm span was between 148.00 and 162.00 cm (Fig. 2). The arm span showed significant positive correlation (r=0.89, p=0.000) with the stature (Figure 3). The multiplication factor (M.F.) regarding the arm span for estimating stature is mentioned in Table I. In this study, arm span was multiplied by mean multiplication factor and then estimated stature was obtained and then calculating the mean for 100 estimated values. This is shown in Table-II.

DISCUSSION: Although there was no similar study in the said population to analyze the results of the present study and to compare with other studies, some observations may be worth mentioning. The mean arm span of the subjects of the present study was 149.26±5.82. Higher value was seen in the Caucasian such as Spaniard females and Afro-Caribbean (Negroid) studying in the Oxford university⁹. Oriental groups were almost similar in their mean arm span value to a greater extent¹⁰. Afro-Caribbean had the highest mean arm span among the arm span considered⁹. As the Chakma tribe belongs to the Mongoloid race, some similarities are expected to exist with the other ethnic groups of Mongoloid race but we have found that variation is present among mongoloid race also. A study on Malaysian females showed mean arm-span nearer to this value of the Chakma females¹¹. If we see the other ethnic groups such as Urban Bengali females, South and North Indians females¹²,¹³ of India and Asians studying in Oxford Brooks University¹⁰, we have found that all of them considered in this study showed higher value than this. In the present study, the mean stature of the Chakma females was found as 148.74± 5.34 centimeters. The mean stature of the Japanese and Chinese females has been found somewhat closer to this value. The urban Bengali females¹² and the females of some Indian ethnic groups like South Indians¹ appear to show a higher mean stature than the Chakma females. However, rural Bengali females¹⁴ and Indians like Santhals of West Bengal¹⁵ had lower value than the Chakma female population. A little higher value was observed in Bangladeshi Garo females⁵. Higher mean stature was also being noted in the Caucasian females of Mexican⁶ origin. It should be noted that the highest mean stature was found in the Negroid adult females like the Somali in Ethiopia⁴. From the above view it may be suggested that variation is not only present in between races or ethnic groups but also present among individual races or ethnic groups.

CONCLUSION: Though the sample size was small and the convenience sampling had to be applied due to time constraints as well as because the study was done on such a group of people where a sampling frame could not be constructed, results of the present study will provide a baseline information, regarding some variables of a particular population (defined for the present study as Chakma females). It could be lead to the development of a standard for such data on various subgroups of the population (and the population as a whole). Comparisons made with other population could contribute to the understanding of the relative status of our Chakma population in the context of the anthropometric variations around the world. Significant correlations, as detected in the study between some of the measurements and their implications in the development of proper multiplication factors to be useful in estimating one measurement from another. This should encourage others in taking up further research in the field. A similar study might be done on other tribes like Tipra, Jamatia, Reang, Murong and others, and relationship of stature with other parameters (lower limb dimensions etc.) of the body could also be considered.
