ABSTRACT

BACKGROUND

Anaemia during pregnancy is considered as an established risk factor for both mother and foetus. Serum ferritin is the most sensitive parameter of negative iron balance, as it decreases only in the presence of true iron deficiency as with transferrin saturation.

AIMS AND OBJECTIVES

The aim of the present study was to compare the normal serum ferritin levels and haematological parameters between non-pregnant women and pregnant women in all three trimesters.

MATERIALS AND METHODS

This study was conducted on 20-30 years aged pregnant and non-pregnant women, who were above upper class. Serum Ferritin, Haemoglobin, Blood Indices, RBC tests were done at central laboratory in ASRAM College, Eluru, A.P. Serum ferritin test was done by using UBI MAGIWEL Enzyme immunoassay ferritin kit, on ELISYS-UNO instrument. We excluded diabetic, obese and any chronic disordered women. Height and weight were measured with the subject in light clothes without shoes and Body Mass Index (BMI) was calculated as kg/m². Statistical analysis was done by using Microsoft Excel 2010. ANOVA and T test were done to analyse data.

RESULTS

Serum ferritin levels were significantly lower in 2nd trimester of pregnancy and we observed increase in serum ferritin levels in 3rd trimester of pregnancy. These results indicate fall in MCV, MCH and MCHC showed a linear correlation with serum ferritin level. Serum ferritin levels were higher in non-pregnant women, but decreased during three trimesters of pregnancy. Thus, it is proved serum ferritin levels decreases during pregnancy even in above upper class women.

CONCLUSION

In our study, we observed decrease in serum ferritin levels. Decrease in serum ferritin levels were the better indicator of iron deficiency anaemia. Iron deficiency anaemia may be due to improper food supplementation during pregnancy period, lack of meeting dietician and improper diet.

KEYWORDS

Ferritin, Haematological Profiles, Pregnancy.

INTRODUCTION

Iron absorption and iron balance is varied in men and woman. Adult men need 1 mg/day and menstruating woman need 1.5 mg/day. Pregnant woman need higher levels, which is about 4-5 mg/day. However, lower serum ferritin levels were observed in many studies during three trimesters of pregnancy. Anaemia is the leading cause for haematological disorders in female children and it is also an effective cause in pregnant women. Iron deficiency is one of the causes of future disorders, especially in women's menstrual and pregnant life. If iron is not supplemented, most of women may develop iron deficiency anaemia. Micronyctosis is a sensitive index of iron deficiency, but its values are limited because of physiological increase in MCV, that often occurs during pregnancy.

Serum transferrin is frequently abnormal in pregnancy. Anaemia during pregnancy is considered as an established risk factor for both mother and foetus. It is well known that haemoglobin concentration falls during pregnancy principally as a result of haemodilution. Low sensitivity of transferrin saturation, day-to-day and even hour-to-hour fluctuation of serum iron levels renders us to evaluate serum ferritin levels for diagnosing iron deficiency.

Several studies have proven that serum ferritin is the single best non-invasive test and is a very useful and reliable index of iron stores, especially during pregnancy with low levels indicating iron deficiency. There is only one limitation with serum ferritin estimation, as it is an acute phase reactant and it is not a sensitive indicator of iron stores in those suffering from an infection, inflammation or cancer. In recent years, the serum Transferrin Receptor (TfR) level has been introduced as promising new tool for diagnosis of iron depletion. It was observed imbalance in iron supplementation may lead to iron deficiency anaemia and improper foetus growth disorders. Incidence of low birth weight children is associated with anaemia and disorders during pregnancy.
Ferritin is stored in almost all tissues of human body and small amounts are released into the serum, where it functions as an iron carrier, thus deficiency of serum ferritin may indicate iron deficiency anaemia.\textsuperscript{14}

**MATERIALS AND METHODS**

This study was conducted at ASRAM Hospital, Eluru in Central Lab before they take breakfast. Participants were non-pregnant and pregnant women in different trimesters and 20 persons were considered in each group. Totally, study was conducted on 80 females and having age 20–30 years.

In this study we compared serum ferritin levels between non-pregnant and pregnant women, also examined haematological parameters such as RBC, Hb, PCV, Blood Indices (MCV, MCH, MCHC). Ferritin levels were identified by using UBI: MAGIWEL Enzyme immunoassay ferritin kit, by using ELISYS-UNO instrument. Haematocrit levels were identified by performing Wintrobe’s method. Haemoglobin levels were calculated by using RBC, Hb, PCV values.

We excluded diabetic, obese and any chronic disordered women. Height and weight were with the subject in light clothes without shoes and Body Mass Index (BMI) was calculated kg/m\textsuperscript{2}.

The considered subjects were interviewed and basic history was taken into consideration. The subjects were given proper precautions and self-consent form was taken before drawing blood.

Statistical analysis were done by using Microsoft Excel 2010. ANOVA and T test was done to analyse data. Ethical Committee permission was taken. The results of the study were expressed as mean±standard deviation. P-value <0.05 was considered statistically significant.

**RESULTS**

Haematological parameters such as RBC, Hb, PCV, Blood Indices (MCV, MCH and MCHC) levels were increased in first trimester of pregnant women than in non-pregnant woman. But these levels were decreased in second trimester than the first trimester. When we compare third trimester pregnant women with second trimester women, haematological parameters such as RBC, Hb, PCV, Blood Indices (MCV, MCH, MCHC) were increased than the second trimester of a pregnant woman.

The serum ferritin levels were decreased in first trimester of pregnant women, not much as compared with non-pregnant woman. But serum ferritin levels were decreased in second trimester than the first trimester. In third trimester, serum ferritin levels were increased than the second trimester of a pregnant woman. Finally, we observed serum ferritin levels were high in non-pregnant women than pregnant woman. All the pregnant and non-pregnant women were non-vegetarians. Haemoglobin levels were lesser than normal. When we compare haemoglobin levels in pregnant and non-pregnant women, there is a significant decrease in haemoglobin levels in 2nd trimester of pregnancy.

DISCUSSION

Our study was conducted to find iron deficiency anaemia and serum ferritin levels (as diagnostic marker) in pregnant and non-pregnant women. We observed decrease in serum ferritin levels during the three trimesters of pregnancy, even though people belong to above upper class. Alper BS, Kimber R et al, concluded that in the population of all prenatal patients with anaemia approximately has iron deficiency.6 Martinez H and Greiner T et al, concluded that pregnant women in the third trimester and those who were breast feeding their children during the first six months after delivery had highest prevalence of anaemia.10 Kaneshige, Emiko et al, observed in first trimester of pregnant women the serum iron and ferritin levels increased significantly than non-pregnant women and also they observed during second and third trimesters the serum iron and ferritin levels were decreased significantly.15 These results suggest that maternal iron body storage is depleted during second trimester of pregnancy in those who are not taking supplemental iron.7 Ulmer H U suggests that the determination of serum ferritin levels in pregnancy is necessary for a reliable classification of iron deficiency anaemia.16 Naghmi Asif and Shaheen Mahmud et al, concluded that serum ferritin levels were significantly lower in second trimester with increase again in third trimester and increasing gravidity had no significant effect on serum ferritin levels.6 They concluded that pregnant women in the third trimester and those who were breast feeding their children during the first six months after delivery had highest prevalence of anaemia.7 Theresa O Scholl et al, conclude that iron supplementation may improve pregnancy outcome when the mother is iron deficient, it is also possible that prophylactic supplementation may increase risk when the mother does not have iron deficiency anaemia.17 Akin Bola TS, Adewole IF et al, concluded that only Hb values are lowest in third trimester of pregnant women.18 Their results indicate that low iron levels occur with increasing pregnancy as gestation advances.5 In their study, they observed no significant relationship between occurrence of iron deficiency anaemia and serum ferritin levels in higher economic class individuals.1 In their study, they proved in healthy individuals the concentration of serum ferritin parallels the amount of storage iron.11 In other studies they observed in higher economic group, exhaustion of iron levels during pregnancy may lead to iron deficiency anaemia and however once iron stores become exhausted serum ferritin concentrations no longer reflect the severity of iron deficiency.12 Serum ferritin levels are not at all appropriate indicator of iron deficiency in presence of inflammation during pregnancy.19 Some other studies proved women with normal iron levels at conception, the serum ferritin levels increases initially followed by a progressive fall by 32 weeks.20 Iron supplementary drugs can improve iron levels in women; drugs such as ferrous sulphate (300 mg), ferrous gluconate (320 mg) are preferred and should be given 3-4 times a day. In iron deficiency anaemia patients’ diet rich of cereals, bread, red meat, leafy vegetables, bread can improve iron status in women.21

CONCLUSION

In our study, we observed decrease in serum ferritin levels. Decrease in serum ferritin levels were the better indicator of iron deficiency anaemia. Iron deficiency anaemia may be due to improper food supplementation during pregnancy period, lack of meeting dietician and improper diet.
