ABSTRACT

BACKGROUND
Anterior cruciate ligament injuries contribute to the major ligament injuries involving the knee. What we thought of isolated anterior cruciate ligament (ACL) injuries were not isolated injuries, there are associated posterolateral, posteroomedial, anterolateral corner injuries and meniscal injuries. Identifying these injuries is of paramount importance to prevent the knee from developing arthritic changes in the future.

Objectives: To know the spectrum of posterolateral corner injuries in ACL injured knee.

MATERIALS AND METHODS
Patients who came to Radiology Department of Government Medical College, Kozhikode with positive history and symptoms of ACL injury, of which there was MRI evidence of ACL injury, were taken for studying the prevalence of posterolateral corner injuries. The study period was from January 2015 to September 2016.

Type of Study- Descriptive study.
Inclusion Criteria- Positive history of ACL lesion. Positive one or two ACL lesion physical tests (the Lachman, anterior drawer test and pivot test).
Exclusion Criteria- Patients <18 yrs. and >80 yrs. ACL injury with knee dislocation.

RESULTS
Posterolateral (PL) corner injuries showed prevalence of 5.1% and all the cases were in grade 3 ACL injured knees. Isolated lateral collateral ligament showed prevalence of 10%.

CONCLUSION
In cases of ACL injury undergoing MR imaging, posterolateral corner injuries have to be specifically looked and reported for better management of the patients.

KEYWORDS
Prevalence, ACL, Posterolateral Corner.

BACKGROUND
Knee injuries are one of the common problems in orthopaedics which include fractures and ligament injuries. Among the ligament injuries, anterior cruciate ligament (ACL) injuries account for the bulk of the injuries.

Now everyone recognises the importance that ACL is the primary restraint of anterior translation of tibia.

Even now the debate continues whether to surgically repair the isolated ACL tear. Advocates of these groups say isolated tear of ACL alone can be managed by muscle strengthening exercise. The issues with regard to the isolated ACL injuries is that over the time there is increase in associated medial meniscus injury and osteochondral defects leading to secondary osteoarthritis.1-6 With advanced imaging and arthroscopic techniques, we came to know that what we thought of isolated ACL injuries were not isolated injuries.7 There are associated posterolateral, posteroomedial or anterolateral corner injuries and meniscal injuries. Identifying these injuries is of paramount importance to prevent the knee developing arthritic changes in future.

Regarding the surgical management of ACL injury, present scenario is arthroscopic intra-articular reconstruction of the ligament with either hamstring tendon graft (Single bundle or quadruple bundle) or bone patellar tendon graft.
Lateral corner of the knee can be divided into anterolateral and posterolateral corner. Posterolateral corner is stabilised by the arcuate ligament complex which consists of lateral collateral ligament; biceps femoris tendon; popliteus muscle and tendon; popliteal meniscal and popliteal fibular ligaments; arcuate ligament, lateral gastrocnemius muscle and fabellolabular ligaments. Most of the injuries involving the lateral corner injuries can be evaluated by MR imaging by routine spin echo sequences in the sagittal, coronal, and axial planes.

When comparing the injuries involving the medial and lateral structures of the knee, lateral quadrant injuries are less common than medial quadrant injuries; however, the lateral quadrant injuries are more disabling than medial quadrant injuries. And moreover, lateral quadrant injuries are associated with injuries to the cruciates and injuries to the medial corner. These types of injuries are frequently missed in the clinical examination.

MATERIALS AND METHODS
Patients who came to Radiology Department of Government Medical College, Kozhikode with positive history and symptoms of ACL injury, of which there was MRI evidence of ACL injury, were taken for studying the prevalence of posterolateral corner injuries.

Methodology
Research Design
Cross sectional study.

Duration of Study
For a period of one and half years.

Study Setting
Department of Radiodiagnosis, Government Medical College, Calicut.

Study Period
Starting from January 2015 to September 2016.

Study Subjects
Patients above 18 and less than 80 years who had MR imaging evidence of ACL injuries were taken up for study.

Inclusion Criteria
- Positive history of ACL lesion.
- Positive one or two ACL lesion physical tests (the Lachman, anterior drawer test and pivot test).

Exclusion Criteria
- Patients <18 yrs. and >80 yrs.
- ACL injury with knee dislocation.

Sample Size
Sample size was calculated using the formula n=Z²pq/d².
(Z=1.96, expected p=20. (Prevalence was taken assuming that 20% of the patients are having positive anterior and posterolateral corner injuries).
q = 100-p=80, precision=7%).
N=3.96X20x80/49= 120.

Study Method
Basic data and patient information was collected using proforma which include name, age and sex, involved side of knee, brief patient history and physical examination findings. Patients were selected for the study on the basis of injury involving the ACL and these injuries were graded into three grades; Grade 1: partial tear with less than half of the ligament substance disrupted; Grade2: partial tear with more than half of the ligament substance disrupted; Grade3: complete tear.

Injuries involving the posterolateral corner assessed according to the involvement of lateral collateral ligament, popliteus tendon, fabellolabular ligament, arcuate ligament by the hyperintense signals and bulkiness of the structures in T2 and PD weighted images, and discontinuity in the fibres in various grades of ACL injured knees.

MRI Protocol
MRI done with a 1.5 Tesla (GE HDXT) 16 channel with 18 superconducting shim coils and a dedicated 8 channel 13 element phased array knee coil with patient lying supine. The imaging protocols include mainly T1-weighted images in the axial plane (TR/TE, 400–700/9–16), T2-weighted images with fat saturation in the sagittal and coronal planes (TR/TE, 3200–4500/40–50), T2*-weighted images in sagittal (TR/TE 400-600/15-25) and FS PD-weighted images in axial, sagittal and coronal planes (TR/TE 3,000-4000/40-50) with slice thickness of 3 mm and spacing of 0.5 mm.

Statistical Analysis
- Data was coded and entered in MS excel. Analysis was done using SPSS version 18.
- Frequencies of PL corner Injuries of knee were assessed as percentages.
- Association of PL corner injuries in various Grades of ACL assessed were expressed in percentages. Statistical test used was chi square test.
- P value <0.05 were taken as significant.
- Different statistical analytical methods were used to analyse the data.

Variable under Study
Spectrum of posterolateral corner injuries in various grades of ACL injured knees.

Measurement of Variables
Using T2 weighted sequences with fat saturation and proton density sequences.

Ethical Aspects
Study protocol was submitted to the institutional research committee as well as institutional ethics committee of Govt. Medical College, Kozhikode and clearance was obtained for conducting the study.

Case 1 showing injuries involving the popliteus tendon and popliteofibular ligament, the fabellofibular ligament, the biceps femoris tendon.

Case 2 Showing injuries involving the posterolateral corner
RESULTS
We studied MRI of ACL injured knees for knowing the prevalence of posterolateral corner injuries in 180 patients who came to the Department of Radiology, Government Medical College, Calicut from January 2015 to September 2016.

In our study, majority of the patients with ACL injury were male (78%) and showed equal involvement of right and left knees. A study by Csintalan showed higher incidence in male patients.

Among the various grades of ACL injured knees, 44% cases showed grade 3 tear.

Posterolateral corner injuries were seen in 4 cases (5.1%) with all the cases noted in Grade III ACL injuries. All these cases showed injury involving the popliteal tendon and lateral collateral ligament.

Injuries of the isolated lateral collateral ligament injuries were noted in 7.1% cases of grade 1 ACL injured knees and 8.5% and 10% cases of grade 2 and grade 3 ACL injured knees. A similar study by LaPrade RF et al showed 16% incidence of posterolateral injuries of knees when considering all ligament injuries. No separate incidence for each ACL and PCL injuries is mentioned in these articles.

An article by Bonadio quotes the occurrence of posterolateral corner in 2% cases.

An article by Vinson et al quotes that with imaging alone it is difficult to define, when the instability of knee exists. With the available data, it can be observed that tear of two or more of the posterolateral structures (Especially LCL, popliteofibular ligament, posterolateral joint capsule) suggest the diagnosis of high grade PL corner injuries.

According to this, our study showed only 4 cases with high grade PL corner injuries. Sixteen cases showed involvement of isolated LCL injuries in the various grades of ACL injured knees which was not statistically significant.

CONCLUSION
Majority of the anterior cruciate ligament (ACL) injured knees were noted in male patients and showed equal distribution in right and left knees.

All the PL (Posterolateral) corner injuries were noted in grade 3 ACL injured knees.

The knowledge about the anatomy and biomechanics of lateral corner injuries are researched and published.

In cases of ACL injury undergoing MRI, PL corner injuries have to be specifically looked and reported for better management of the patient.
