TRANSVAGINAL PELVIC SCAN ALONG WITH SONOHYSTERO-SALPINGOGRAPHY IN EVALUATION OF INFERTILITY

Narayani. B.H¹, Shukla Shetty².

HOW TO CITE THIS ARTICLE:

ABSTRACT: Background and Objective: Infertility is a common complaint during the reproductive age group and accounts for much medical and surgical intervention. Sonohystero-salpingography is a cost effective, safe, non-invasive and painless procedure to visualize the female pelvic organs in the evaluation of infertility. The purpose of this study is to find out the factors responsible for female infertility in single sitting using non-invasive, painless and acceptable procedures.

METHODS: 50 infertile women were included for the study. After taking consent, all the women were subjected to TVS along with sonohystero-salpingography in the same sitting between 7th and 11th day of menstrual.

RESULTS: The factors responsible for infertility namely uterine, ovarian and tubal detected compared with other standards studies. Interpretation and Conclusion: TVS along with sonohystero-salpingography can be used as primary diagnostic tool in the overall assessment of factors responsible for infertility. It is simple safe, non invasive and avoid unnecessary diagnostic procedures.

KEY WORDS: Infertility, Sonohystero-salpingography, Uterine factors, Tubal factors, Ovarian factors

INTRODUCTION: Various diagnostic procedures are available to evaluate the anatomy and function of the ovaries, uterus and the fallopian tubes. Ultrasound examination for the anatomy of the uterus, tubes and ovaries may give sufficient information and can be modality of investigation over the other.¹ The aim of the study was to evaluate all women who presented with primary or secondary infertility and to find out uterine, tubal and ovarian factors responsible for female infertility with the use of ultrasound.

METHODS: The present study was carried out on 50 infertile women who attended Obstetric and Gynecology Departments of the Hospitals attached to J.J.M. Medical College during the period from November 2005 to September 2007.

Inclusion Criteria: Primary and Secondary infertile women in the reproductive age group.

Exclusion criteria: Patients having active pelvic infection, active vaginal bleeding, malignancy of the genital tract, and abnormal semen analysis of the Husband. All eligible patients were properly counseled and gave informed consent before entry into the study. Detailed menstrual, obstetric and medical histories of each patient were obtained and general physical, systemic and gynecological examination was performed. Relevant investigations were performed according to clinical findings. All the 50 patients were subjected to Trans-vaginal scan along with saline infusion Sonohystero-salpingography in the same setting to visualize the uterine contour, contents, ovaries and the fallopian tubal patency. This procedure was performed between 7th and 11th day of the menstrual
cycle. Initially the patients were evaluated with an abdominal transducer. Then TVS was done to note endometrial thickness, uterine or ovarian abnormality and later normal saline 20-30 ml injected into the uterus through Foley’s Catheter 8 French to know the tubal patency and to look for endometrial polyp. The right and left ovarian fossae, paracolic gutters and the pouch of Douglas was visualized. Flow of fluid and air – “Turbulence” was looked for in the region of right and left ovarian fossae and this “turbulence”- “The waterfall sign” was taken as patency of the respective fallopian tube. Later the cul de sac was also visualized to look for free fluid. (Fig 1 & 2)

**RESULTS:** In the study 22 cases (44%) were in the age group of 20-24 years. 23 cases (46%) were in the age group of 25-29 years, 3 cases (6%) were in the age group of 30-34 years. 4% cases were in age group above 35 years. The minimum age of the patient was 20 years and the maximum age of the patient was 38 years. The mean age of the patient was 25.18 years (range 20-38 years).

In this study of infertile women overall incidence of primary infertility was found to be 68% (34 cases) and secondary infertility was 32% (16 cases). In the present study 20 cases (40%) were of 1-4 years of infertility. 26 cases (52%) were having 5-9 years of infertility. 4 cases (8%) were having 10-12 years (range-1.5-12 years). In the present study menstrual pattern was normal in 18 cases (36%), 14 cases (28%) presented with oligomenorrhea, 10 cases (20%) presented with menorrhagia, 3 cases (6%) presented with amenorrhea, 2 cases (4%) presented with hypomenorrhea, 3 cases (6%) presented with metrorrhagia. Most common abnormal menstrual pattern was Oligomenorrhea. By using TVS uterus was found to be normal size in 43 cases (86%)
while in 7 cases (14%) it was enlarged. In this study 11 cases (22%) had endometrial thickness of 3.1-5.9 mm, 34 cases (68%) had thickness of 6.0-12.0 mm. More than 12 mm was seen in 3 cases (6%) and endometrial echo was absent in 2 case (4%). Mean endometrial thickness was 8.5 mm. The range was 3.1-14.6mm in 48 cases, excluding 2 cases with absent endometrial echo. In the present study transvagal scan revealed normal ovaries in 38 cases (76%) on right side and 36 cases (72%) on left side and bilaterally enlarged ovaries seen in 8 cases (16%). Bilaterally small ovaries were seen in 2 cases (4%). Ovaries on right side were replaced by tubo-ovarian mass in 2 cases (4%) and on left side in 4 cases (8%). Study also shown that polycystic ovary was seen in 8 cases (16%). Dominant follicle in any one ovary was present in 29 cases (58%) and was absent in 21 cases (42%). (Table i) (Fig 3)

**Adnexal abnormality in infertile women**

In the present study no uterine pathology was identified in 40 cases (80%) while pathology was identified in 10 cases (20%) submucous fibroid (Fig 4) was seen in 2 cases (4%) multiple fibroids were seen in 2 cases (4%), posterior wall fibroid seen in 1 case (2%), intramural fibroid seen in 1 case (2%), adhesion were seen in 1 case (2%), combination of adhesion and intramural fibroid seen in 1 case (2%), polyp seen in 2 cases (4%). **Fibroids in infertile women**

Fluid in Cul de sac was demonstrated in 46 cases (92%) and in 4 cases (8%) it was absent. Bilateral patent tubes were seen in 38 cases (76%). In this study 12 cases (24%) had minor complaints like lower abdominal pain. 38 cases (76%) did not have any complaints. 1 case (2%) had complication like peritonitis and other 49 cases did not have any complication. In this study primary infertility patients showed fibroid and or polyp in 5 cases (14.7%) while in secondary infertility patients it was 4 cases (25%). Even though the incidence of fibroids and or polyp is increased in secondary infertility but is statistically insignificant ($X^2 = 0.24, P > 0.05$). Present study revealed PCOS in patients with age ≤ 25 years in 5 cases (18.5%) and in patients with age > 25 years it was present in 3 cases (13%), however it is statistically insignificant (p > 0.05) Fibroids was present in 2 cases (7.4%) of the patient with age < 25 years and was present in 7 cases (30.4%) in patients with age > 25 years it revealed the incidence of fibroids increased with age of the patient and it was statically significant ($X^2 = 4.46 & P < 0.05$) In the present study ovarian asymmetry with dominant follicle in any one ovary with late proliferate endometrium seen in 29 cases (58%). Bilateral symmetrical ovaries with no follicular activity and thin endometrium seen in 11 cases (22%). Bilaterally enlarged ovaries with cysts arranged in necklace pattern (PCOS) with different patterns of endometrium seen in 8 cases (16%) comparable to study by Prasad S 4 (8.8%) is almost double whereas it is comparable to study by Rahman, Sinha 2 (13%). Bilateral small ovaries with absent endometrial echo in 2 cases 4%.

Follicular activity in infertile women

**DISCUSSION:** Fertility peaks by 25 years of age and 1/3rd of women are no longer fertile by 40 years of age. Since the fertility of women decrease progressively with age particularly after 30 years, so earlier the patient is investigated for infertility the better the chance of success. Present study shows that trans-vaginal scan along sonohystero-salpingography done in single sitting in the infertility work up gives overall assessment of women including uterine factors, ovarian factors, tubal factors and also endocrine factors (hormonal status). Which are comparable with other investigation modalities for tubal patency like hysterosalpingography (HSG), laparoscopy, whereas trans-vaginal scan along with sonohysterosalpingography can be used a simple, non-invasive, with no exposure to radiation in the evaluation of infertility patient. Thus, we can save a large number of unnecessary invasive diagnostic procedure, money, and discomfort to the patient.

Hence it is recommended that TVS along with sonohystero-salpingography should be used as primary investigation modality in infertile women after evaluating the partner.
