ABSTRACT

BACKGROUND
Fever is the most common presentation of any infection, which can lead to grave prognosis of maternal and foetal outcome if not managed timely. So, this study was conducted to find out the aetiology and outcomes of fever in pregnant women.

MATERIALS AND METHODS
An observational study was conducted in Dr. BSAMCH, New Delhi. A total of 180 women admitted with fever during pregnancy from June 2016 to September 2016 were included in the study and managed according to hospital protocol. The aetiology, maternal and neonatal outcomes were noted and evaluated. Results were analysed on excel sheet.

RESULTS
Out of 180 women 33.33% were diagnosed with typhoid, 25% had viral fever, 11.6% with UTI, 5.56% with malaria and 0.5% with chikungunya. Approximately, 22.3% women had both typhoid and dengue. After treatment, 56.66% (n=102) of women were discharged in good foetal well-being condition. Twenty three percentage (n= 42) women had full-term normal vaginal delivery, 12.23% (n= 22) had preterm vaginal delivery and 7.78% (n= 14) underwent caesarean section. Two dengue patients had intrauterine foetal demise and they expired in postpartum period. Eleven neonates from preterm delivery required NICU admission.

CONCLUSION
The common causes of fever in pregnancy were typhoid, dengue and viral fever. Dengue fever was most fatal of all aetiologies. So rational and individualised approach in managing these patients with low threshold to admit them could be life saving for both mother and foetus.

KEYWORDS
Pregnancy, Fever, Maternal Outcome, Foetal Outcome.

BACKGROUND
Pregnancy leads to a lot of changes in women’s body. It is a state of lower immunity in order to accept a foetus, which is foreign to her. Simultaneously, this lead to the altered susceptibility and severity for infectious disease in pregnancy. Fever is the most common presentation of any infection. Mother and foetus both are affected by the infection as well as the fever. As India being a country of tropical areas and very prone for epidemics of various diseases, thus we have conducted an observational study to find out the aetiology and outcome of fever in women in antenatal period that required admission.

MATERIALS AND METHODS
An observational study was conducted in a tertiary health care centre in North Delhi region. All women with fever in antenatal period who were admitted from June 2016 to September 2016 were included in the study. Women having sign of septicamia or chorioamnionitis had been excluded from the study. A total of 180 women were admitted with history of fever in antenatal period. Illness history, clinical examination and clinical evaluation were recorded. A series of tests including fever profile, blood tests, urine tests and ultrasound were conducted and management done according to hospital protocol. Results were analysed on the spread excel sheet.

RESULTS
Most of the women were from suburban area of North Delhi. All of the women belonged to low socioeconomic status. Almost, 41% of women who were in the age group of 20 - 25 years. Only 28.09% of women were primigravida and rest were multigravida. There were 10.46% (n= 19) of women in 1st trimester, 30.32% (n= 55) of women in 2nd trimester and 58.88% (n= 106) of women in 3rd trimester. All women were initially started with empirical management followed by specific management according to the result of the investigations. Duration of stay were ranging from 2 days to 11 days with a mean duration of 6 days. Around 68% of women stayed for 2 to 7 days, 26.78% stayed for more than 7 days and 5.22% of women stayed for less than 2 days. A total
of 33.33% (n= 60) of women were diagnosed with typhoid, 25% (n= 45) with viral fever, 22.23% (n= 40) with dengue, 11.6% (n= 20) with UTI, 5.56% (n= 10) with malaria and 0.05% (n= 1) with chikungunya. Approximately, 2.23% (n= 4) women had both typhoid and dengue (Table 1).

Clinical presentation along with fever were malaise, chills, rigors, pain abdomen, burning micturition, diarrhoea, reduced or no foetal movement. Comorbidity in the form of anaemia, preeclampsia and gestational diabetes was found in 32.43% of women.

Among antenatal women, after treatment 56.66% (n=102) of women were discharged in good foetal well-being condition and 12 women went LAMA (Leave against medical advice) in antenatal period, whereas in postnatal period eight women went LAMA. A total of 43.34% (n= 78) women were delivered with 23.42% (n= 42) vaginal delivery, 12.23% (n=22) preterm vaginal delivery and 7.78% (n= 14) caesarean section. None of the women were induced for foetal movement.

Around 12.23% (n= 22) women landed up in preterm vaginal delivery and 6.11% (n= 11) neonates required NICU care. However, all neonates were discharged in satisfactory conditions except one still birth. Two women with dengue had delivered macerated still born and expired in postpartum period. One of them had landed up in preterm vaginal delivery and the other one underwent caesarean section (Fig.1).

Fever is a defense mechanism against any infection in the body and it is difficult to distinguish the effects of fever from those of an underlying infection. Maternal fever is not uncommon during pregnancy, but the outcome can have varied pictures as it affects the health of both the mother and the foetus and increases the morbidity and mortality of both. The consequences depend on aetiology of fever and period of gestation at which infection occurs. Range and duration of fever are independent factors, which affects outcome. Pregnancy is a state of low immunity, hence any infection (viraemia or bacteraemia) can precipitate easily.

Studies reported that one in five women experience fever once in pregnancy. India being a tropical country with lots of diversity in weather leading to epidemic of many diseases. The study being conducted between June to September, which is the season of many epidemics in India.

All women in our study belonged to low socioeconomic group and from suburban area, which is per se indicative of lack of awareness and less availability of resources for the better well-being and so making them prone to many epidemic diseases.

There were 58.88% women in third trimester of antenatal period. Studies have shown the relation of fever in pregnancy with the birth defect in early trimester. Edward et al found hyperthermia is a known cause of congenital defects of the central nervous system and other organs after sufficiently severe exposures during early organogenesis. But in our study, most of the women were in the second or third trimester of pregnancy. So it was less likely that they will develop the congenital anomalies.

A surprising finding of 33.33% of women were with typhoid fever, which again emphasised the poor orofaecal route of contamination due to poor hygiene and low socioeconomic status, whereas it was rare in European countries.

There were 22.2% (n= 40) of women suffering from dengue and two women in this group had expired. It is the most fatal disease in our study group leading to mortality, which was also seen in the study by Swati et al. Study by Mac Grady R suggested that malaria is still the leading cause of fever in pregnancy, but we found only 5.56% (n= 10) women were suffering from malaria in our study group.

There were 11.1% (n= 20) who had UTI and five women underwent preterm labour. The study by Dimetry SR et al and Marziyeh A et al also showed the high incidence of preterm birth in women with UTI.

A systemic review by Dreier showed that maternal fever during pregnancy may negatively affect offspring health. Studies have been suggested that temperature more than 102 Fahrenheit and for a longer duration (more than 7 days) can lead to neural tube defect or infantile autism, but in our study only 10% of women with temperature more than 102 Fahrenheit
Fahrenheit and none of them had fever for more than seven days.\(^{12,13}\)

However, most of our women are in 2\(^{nd}\) or 3\(^{rd}\) trimester, but we do not have the follow-up, so we are not able to find long-term adverse effects on child as suggested by Dombrowski et al and by Calvani et al.\(^{14,15}\)

Surprisingly, we found that 35% of patients who had fever went into labour and had vaginal delivery irrespective of the cause of fever. There were 12.23% women who landed up in preterm vaginal delivery and 11 babies required NICU care. The possible mechanism for this is due to the cascade of mediators released by active host inflammatory response to infection exerts distant effects on the uterus leading to preterm labour during the course of febrile illness due to viral or bacterial infections. On reviewing the literature, we did not find any study showing relation between fever and labour.

Limitation of the study was that it was for shorter duration and the result of study required long-term follow-up.

CONCLUSION

The common causes of fever in pregnancy in the present study were typhoid, dengue and viral fever, and dengue fever was the most fatal in all. Low threshold to admit these patients is mandatory and life saving for both mother and foetus. Vector control methods should be employed during seasonal outbreaks. Awareness programs and medical education programs on the management of foetal epidemic fever in pregnancy should be initiated, especially during outbreaks to provide quality care. Larger and increased duration studies in all gestational age are required to find out its sequels in pregnancy outcome.
