PATTERN OF CHEST INJURIES IN FATAL ROAD TRAFFIC ACCIDENTS- AN AUTOPSY STUDY

Ravi Kumar K¹, Rajeev V. M²

¹Junior Resident, Department of Forensic Medicine, Government Medical College, Kottayam, Kerala, India.
²Associate Professor, Department of Forensic Medicine, Government Medical College, Kottayam, Kerala, India.

ABSTRACT

BACKGROUND
India is a signatory to the Brasilia declaration and is committed to reduce the number of road accidents and fatalities by 50% by 2020. However, with one of the highest motorisation growths in the world accompanied by rapid expansion in road networks and urbanisation over the years, our country is faced with serious impacts on road safety levels. Trauma to the chest is the second most common injury found in road traffic accidents. Chest injuries accounts for 25% of deaths in trauma victims. It is second only to traumatic brain injury in mortality.

The aim of this study is to analyse the pattern of chest injuries in fatal road traffic accidents.

MATERIALS AND METHODS
An autopsy-based descriptive analysis was conducted.

Sample Size- A total of 161 cases of fatal road traffic accidents with chest injuries was studied during the period of 12 months from 04.02.2016 to 03.02.2017.

Source Population- All cases of fatal road traffic accidents with chest injuries brought for post mortem examination to the Department of Forensic Medicine, Govt. Medical College, Kottayam during the study period was included in the study.

Inclusion Criteria- All autopsies in which death was due to chest injuries in road traffic accidents were included in the study.

Exclusion Criteria- All unidentified bodies and cases in which proper history was not available.

Data Collection- Baseline data like age, sex, height, weight and a brief history of the case were collected from the relatives and investigating officers. A detailed information regarding the nature, time of accident, type of vehicle involved, and category of victim were recorded from the investigating officer and hospital records in case of treated cases. Details of external injuries and chest injuries are recorded in the proforma.

Analysis- Data collected was entered in MS-Excel and analysed using IBM SPSS Version 16.

RESULTS
Among the 161 cases of fatal road traffic accident victims with chest injuries, 136 (84.5%) were males and 25 (15.5%) were females. Maximum number of victims, 57 (35.4%) were in the age group of 45 - 60 years. Maximum number of accidents, 34 (21.1%) occurred in the month of August and least occurred in the month of October (3.1%). Maximum number of accidents (41.6%) occurred during the time 12 PM to 6 PM and least occurrence (4.3%) was between 12 AM to 6 AM. Two wheelers were the commonest vehicles involved (53.4%) followed by car (31.7%). In case of collisions, cars colliding with two wheelers was the commonest (14.3%) followed by two wheelers colliding with heavy vehicles (13%). Majority of victims involved were pedestrians (38.5%) followed by motor cyclists (35.4%). Among the motor cyclists, those wearing helmets were 17 (10.6%) and those occupants with seat belts were only 2 (1.2%). Among the driver, 22 (13.7%) were under the influence of alcohol and among the other victims 29.2% have consumed alcohol. Among the fatal cases 10.6% died on the spot, 38.5% died within 6 hours and 41.6% died within 24 hours. Sternum was fractured in 34.2%, bilateral rib fractures seen in 54.6% and unilateral fracture in 45.4%. Regarding fracture of thoracic vertebrae, the 4th thoracic vertebra was fractured in 11 (6.8%) followed by fracture of 1st and 12th thoracic vertebrae in 4 (2.5%) cases each. Both clavicles were fractured in 6 (3.7%). Right lung showed contusion in 58.4%, while left lung was involved in 65.9%. Laceration of right lung was seen in 40.4%, while left lung was involved in 37.9%. Laceration of aorta was seen in 26 (16.1%) cases. Contusion of heart was seen in 34 (21.1%) cases. Laceration of heart was seen in 6 (3.7%) cases. Associated injury to head was seen in 121 (75.2%) cases. Of which 25.5% had intracranial haemorrhages and 49.7% had fracture of skull. Fracture of cervical spine was seen in 19 (11.8%) cases, while 44.7% showed fracture of any of the limbs. Laceration of liver was seen in 54 (33.5%) and spleen was lacerated in 11 (6.8%) of cases.

CONCLUSION
The mechanism and circumstances of blunt chest injury due to road traffic accidents can be assessed in relation to the number and localisation of rib fractures as well as the presence of injuries to lung, heart and major blood vessels. The most common cause of death 82 (50.9%) was combined injuries to head and chest followed by injuries to head, chest and abdomen 38 (23.6%) and only 6.8% of cases died due to chest injuries alone.

KEY WORDS
Road Traffic Accidents, Chest Injury, Pedestrians, Occupants, Motor Cyclists.

BACKGROUND

Road traffic accidents are a human tragedy. They involve high human sufferings and socio-economic loss in terms of premature deaths, injuries and loss of productivity.1 Nearly, 1.3 million people die every year in the world due to road traffic accidents and 20 - 50 million people suffer non-fatal injuries leading to disability.2 Road traffic accidents are the leading cause of death in young people aged 15 - 29 years and costs countries 1 - 3% of the country's GDP.3 According to WHO, road traffic accidents are the sixth leading cause of death in India with a greater share of economic losses in the young and middle-aged population.4 Seat belt injuries: in severe collisions if the person is wearing seat belt, injuries on the chest and abdomen may be caused. Compression on the chest wall will lead to contusion injuries leading to disability.5

The following table depicts age group distribution of fatal road traffic accidents in Kottayam during the period 04.02.2016 to 03.02.2017.

Table 1: Distribution of Victims based on their Age Group and Gender.

OBJECTIVES

1. To study the pattern of chest injuries in fatal road traffic accidents.
2. To analyse the survival period and cause of death in fatal road traffic accidents.

MATERIALS AND METHODS

An autopsy-based descriptive analysis was conducted.

SAMPLE SIZE

A total of 161 cases of fatal road traffic accidents with chest injuries was studied during the period of 12 months from 04.02.2016 to 03.02.2017.

RESULTS

The study was conducted in the Department of Forensic Medicine, Govt. Medical College, Kottayam during the period from 04.02.2016 to 03.02.2017. A total number of 161 fatal cases in Road Traffic Accidents with chest injuries were analysed on the basis of history and post-mortem findings.

Epidemiology of Fatal Road Traffic Accidents: Gender Wise Distribution

Out of the 161 cases in the present study, majority of the victims were males, 136 cases (84.5%) and 25 cases (15.5%) were females.

Age Distribution

Maximum number of victims (57 cases) belonged to age group of 45 - 60 years followed by age group of 60 - 70 years (35 cases). The following table depicts age group distribution and the corresponding gender distribution.

Source Population

All cases of fatal road traffic accidents with chest injuries brought for post mortem examination to the Department of Forensic Medicine, Govt. Medical College, Kottayam during the study period was included in the study.

Inclusion Criteria

All autopsies in which death was due to chest injuries in road traffic accidents were included in the study.

Exclusion Criteria

All unidentified bodies and cases in which proper history was not available.

Data collection: Baseline data like age, sex, height, weight and a brief history of the case were collected from the relatives and investigating officers. A detailed information regarding the nature, time of accident, type of vehicle involved, and category of victim were recorded from the investigating officer and hospital records in case of treated cases. Details of external injuries and chest injuries are recorded in the proforma.

Analysis

Data collected was entered in MS-Excel and analysed using IBM SPSS version 16.
Time of Occurrence
In the present study, it was observed that maximum number of accidents were seen between 12 PM and 6 PM (41.6%) followed by 6 PM and 12 AM (28%) and least occurrence was between 12 AM and 6 AM (4.3%).

Table 4. Types of Victims Involved
Figure 5. Types of Victims Involved

Distribution of Safety Precautions Adopted by the Victims
Of the 161 cases, 83 persons did not have any safety precautions. 17 cases wore helmets and only 3 cases wore seat belts.

Alcohol Consumption
Out of 161 cases, 69 have consumed alcohol. Among these, 22 cases were either drivers or riders and 47 were pedestrians or occupants of vehicles.

Period of Survival
Of the 161 cases 17 (10.2%) have died on the spot, 62 cases (38.5%) survived for less than 6 hours, while 67 cases (41.6%) survived more than 24 hours and were hospitalised.

Table 5. Table showing Period of Survival

Fracture of Ribs
A rib fracture secondary to blunt thoracic trauma is an important indicator of the trauma. Of the 161 cases studied 88 (54.6%) cases had bilateral rib fractures and 73 (45.4%) cases showed unilateral rib fracture. Out of 161 cases, 149 had haemothorax and 12 cases had no haemothorax.
Fracture of Sternum
Fracture of sternum in direct impact is one of the causes of haemothorax and injuries to heart and pericardium. In the present study, sternum was fractured in 55 cases (34.2%).

Table 7. Distribution of Fracture Sternum in different types of Victims

Fracture of Thoracic Vertebra
Older individuals were found to be almost 5 times more likely to sustain spinal injury compared to younger individuals. Among the 161 cases, 33 cases had fracture of spinal column and 19 cases had fracture of thoracic vertebrae.

Fracture of Clavicle
Among the 161 cases, 78 (48.4%) cases had fracture of clavicle and in 6 cases there was bilateral clavicle fracture.

Fracture of Scapula
It is relatively uncommon. In the present study there were 5 cases (3.1%) of scapular fracture, of which 3 were bilateral.

Lung Injury
Contusion of lung was the most common injury found in blunt trauma to chest. It is usually caused by deceleration that results when the moving chest strikes a fixed object like the steering wheel. Right lung was contused in 62 cases (38.5%). Left lung was contused in 38 cases (23.6%).

Cardiac Contusions
Among the 161 cases, 34 (21.1%) cases showed evidence of cardiac contusion. The favoured sites of cardiac contusions were right ventricle 18 cases (52.9%) and right atrium 16 (47.1%) cases.

Injuries to Aorta
Among the 161 cases in the present study, aorta was injured in 26 (16.1%) cases, of which 16 (9.9%) cases showed involvement of ascending aorta, in 4 (2.5%) cases descending aorta was involved and in 6 (3.7%) cases the arch of aorta was involved.

Region of Aorta
No. of Cases  Percentage
---  ---  ---
Ascending aorta 16  61.5
Descending aorta 4  15.4
Arch of aorta 6  23.1
Total 26  100

Table 8. Laceration of Aorta Region Wise

Site of Chest Injury
Fracture of Ribs (Bilateral) 88  54.6
Fracture of Ribs (Unilateral) 73  45.4
Fracture of Sternum 55  34.2
Fracture of Thoracic Vertebrae 33  20.5
Fracture of Clavicle 78  48.4
Fracture of Scapula 5  3.1
Lung Contusion 100  62.1
Heart Contusion 34  21.1
Laceration of Aorta 26  16.1

Table 9. Distribution of Chest Injuries in Fatal Road Traffic Accidents
DISCUSSION
Pedestrians, cyclists and motor cyclists are the most vulnerable road users accounting for around 46% of global traffic deaths.11 The number of total accidents reported in India during the year 2010 was 499,628.12 The total number of accidents reported in Kerala state during the period 2011 was 35,216.13 Among these, death occurred in 4145 cases. Road traffic accident deaths are higher in men than in women in all regions regardless of income level and across all age groups.14 In India this is partly due to low representation of women in Indian workforce and exposure on roads.15

Among the 161 cases of fatal road traffic accident victims with chest injuries, 136 (84.5%) were males and 25 (15.5%) were females. Maximum number of victims, 57 (35.4%) were in the age group of 45 - 60 years. Maximum number of accidents, 34 (21.1%) occurred in the month of August and least occurred in the month of October (3.1%). Maximum number of accidents (41.6%) occurred during the time 12 PM to 6 PM and least occurrence (4.3%) was between 12 AM to 6 AM. Two wheels were the commonest vehicle involved (53.4%) followed by car (31.7%). In case of collisions, cars colliding with two wheels was the commonest (14.3%) followed by two wheels colliding with heavy vehicles (13%). Majority of victims involved were pedestrians (38.5%) followed by motor cyclists (35.4%). Among the motorcyclists, those wearing helmets were 17 (10.6%) and those occupants with seat belts were only 2 (1.2%). Among the drivers 22 (13.7%) were under the influence of alcohol and among the other victims 29.2% have consumed alcohol. Among the fatal cases 10.6% died on the spot, 38.5% died within 6 hours and 41.6% died within 24 hours. Sternum was fractured in 34.2%, bilateral rib fractures seen in 54.6% and unilateral fracture in 45.4%. Regarding fracture of thoracic vertebrae, the 4th thoracic vertebra was fractured in 11 (6.8%) followed by fracture of 1st and 12th thoracic vertebrae in 4 (2.5%) cases each. Both clavicles were fractured in 6 (3.7%). Right lung showed contusion in 50.4% while left lung was involved in 65.9%. Laceration of right lung was seen in 40.4% while left lung was involved in 37.9%. Laceration of aorta was seen in 26 (16.1%) cases. Contusion of heart was seen in 34 (21.1%) cases. Laceration of heart was seen in 6 (3.7%) cases. Associated injury to head was seen in 121 (75.2%) cases. Of which 25.5% had intracranial haemorrhages and 49.7% had fracture of skull. Fracture of cervical spine was seen in 19 (11.8%) cases, while 44.7% showed fracture of any of the limbs. Laceration of liver was seen in 54 (33.5%) and spleen was lacerated in 11 (6.8%) cases.

CONCLUSION
The mechanism and circumstances of blunt chest injury due to road traffic accidents can be assessed in relation to the number and localisation of rib fractures as well as the presence of injuries to lung, heart and major blood vessels. The most common cause of death 82 (50.9%) was ‘combined injuries to head and chest’ followed by ‘injuries to head, chest and abdomen’ 38 (23.6%) and only 6.8% of cases died due to chest injuries alone.
