ROLE OF USG AND MDCT IN EVALUATION OF URINARY BLADDER MASS

Sunny Goyal¹, Tushar Prabha², Mohan Shivnani³, Ankur Aggarwal⁴, Hemant Kumar Mishra⁵

INTRODUCTION: Primary bladder neoplasms account for 2%–6% of all tumors, with bladder cancer ranked as the fourth most common malignancy (1). Peak incidence is in the sixth and the seventh decades. Incidence is four times higher in men than in women.

The urinary bladder is the organ that collects urine excreted by the kidneys before disposal by urination. A hollow muscular, and distensible (or elastic) organ, the bladder sits on the pelvic floor. Urine enters the bladder via the ureters and exits via the urethra. The bladder is readily identified by ultrasound, Computed Tomography, cystography, Magnetic Resonance Image (MRI) and Cystoscopy, but Bladder ultrasound is noninvasive, readily accessible, and easy to use. It has been extensively investigated as a possible substitution for some of the more common invasive modalities used to evaluate the bladder;(3)

Bladder cancer is the most common tumor of urinary tract. Sonographically, the distended urinary bladder should have smooth, thin, medium level echogenic walls (approximately 3 mm thick) and contain no echoes, with the exception of the normal jets of urine as the ureters empty into the bladder. In the partially filled state, the bladder is collapsed. The urinary bladder cavity is not seen if it is collapsed; otherwise it appears anechoic.

The bladder wall appears as a smooth, thin echogenic line. The sonographic appearances of a partially filled bladder are thickened (up to 6 mm thick), irregular walls encircling an echolucent interior. Therefore, to assess wall thickness, the bladder should be reasonably distended. The ureteral orifices are seen as elevations on the posterior portion of the bladder on longitudinal scans to each side of midline in transverse scans.(4)

SIGN AND SYMPTOMS:

- Hematuria.
- Urgency, frequency and strangury.
- Secondary infections result in cystitis.
- Tumor at bladder base causes obstructive symptoms.
- Pain secondary to clot retention into pelvis and urethral obstruction.
- Constitutional symptoms when distance metastasis occurs.

RISK FACTORS:

- Tobacco smoking.
- Occupation (exposure to aniline, benzidine and 5-naphthylamine).
- Biological agents (coffee, beer, artificial sweeteners, grilled food).
- Exposure to radiation, chronic irritation of urothelium
- Abnormal tryptophan metabolism.
AIMS AND OBJECTIVE:
- To Evaluate the role of USG and MDCT in detection of bladder neoplasm
- To detect the ability of USG and MDCT in staging of malignant neoplasm spread
- To correlate imaging findings of USG and MDCT with Histopathological findings

MATERIALS & METHODS:
Study Location: Radiodiagnosis department of Mahatma Gandhi Medical College & Hospital, Jaipur.
Study Design: Prospective analytical study of case records
Study Population: The study was conducted on patients who were referred from urology, surgery and medicine department with complains of hematuria.

Various types of presentation of bladder mass are as Follows:
- CASE 1: UNIFOCAL MASS.
- CASE 2: MULTIFOCAL MASS.
- CASE 3: MASS AT APEX.
- CASE 4: MASS AS FOCAL BLADDER WALL THICKNING.
- CASE 5: MASS OBSTRUCTING UVJ CAUSING HYDRONEPHROSIS.

</tbody>
</table>
Primary bladder tumors are most common in the age group of 51-70 years and in males.
More common in males who were smokers.
Most common presenting symptom is painless haematuria.\(^{(5)}\)
Majority of Bladder mass are solitary and are at Bladder base and lateral wall.
Most common histological type is Transitional cell carcinoma.\(^{(6)}\)
Transabdominal USG being noninvasive, inexpensive and easily available modality can be used for screening of tumors and initial assessment of staging.
MDCT scan plays a key role in evaluation of bladder neoplasms.\(^{(7)}\)
Tumor extension into adjacent organs and pelvis can be evaluated better by MDCT than USG.\(^{(7)}\)
Lymphnodal and distant metastasis are also better evaluated by MDCT.
No significant difference in size, site, UVJ involvement detection was seen on USG and MDCT.
In majority of cases the nodal metastasis were not well delineated on USG which were observed on MDCT and even bones metastasis if present can be seen on MDCT. Thus, tumor staging can be done by MDCT and USG. However MDCT is superior than USG for detection of distant metastasis.\(^{(7)}\)
