ABSTRACT

BACKGROUND
A number of oxytocic drugs are recommended for prevention of postpartum haemorrhage. Different studies claim superiority of one drug over the other with conflicting results.

Aim- With this background, synthetic oxytocin IM, Inj. Methergine IM and Tab. Misoprostol P/R were used in 3 groups to observe their effects on blood loss, duration of 3rd stage of labour, need for additional uterotonics and adverse effects.

MATERIALS AND METHODS
Settings and Design- Tertiary care centre, Kolkata. Clinical trial, non-randomised with single blinding.

A total of 150 uncomplicated pregnant mothers divided into 3 groups of 50 each were administered inj. Synthetic Oxytocin (Syntocinon) 10 units IM (Group A), Inj. Methergine 0.2 mg IM (Group B) and Tab. Misoprostol 600 mcg P/R (Group C) immediately after delivery of the baby. Vaginal blood was collected in a special receptacle (BRASS-V-DRAPE). Blood loss, duration of 3rd stage, additional uterotonics and adverse effects were noted.

RESULTS
Blood loss and duration of 3rd stage were least with Oxytocin and maximum with Misoprostol with Methergine in between. Additional uterotonics were more often needed with Misoprostol when compared with the other two (Statistically significant). Adverse effects with oxytocin was least.

CONCLUSION
Synthetic oxytocin has more advantages and less side effects compared to other oxytocics used in the study. However, additional uterotonics should be in hand.

KEYWORDS
Oxytocics, Oxytocin, Methergine, Misoprostol, PPH, Uterotonics.

including Hb <8 g%, ii) intrauterine foetal death and iii) coagulation abnormalities. Term pregnancies both booked and unbooked, admitted through OPD or emergency were subjected to thorough history taking, examination and investigations. Details of management were noted. Blood loss collection tool used to assess post-delivery bleeding was with BRASS V DRAPE [Fig. 1]. It was developed by NICHD global network UMKC/JNMC/UIC collaborative team to specifically estimate blood loss in postpartum 48 hours. The drape has a calibrated and funnelled collecting pouch incorporated within a plastic sheet that is placed under the buttocks of the patient immediately after delivery of the baby. The upper end of the sheet has a belt for tying loosely around the abdomen of the woman [Fig. 2].

Procedure
- On admission into the labour room, pre-delivery vital signs and Hb% were recorded.
- First and second stages of labour were monitored.
- Calibrated BRASS-V-DRAPE was kept under the buttocks after the delivery of the baby so that blood could collect in the receptacle.
- Umbilical cord was clamped, cut and baby handed over.
- Oxytocic drug was administered by the assistant immediately after delivery of the baby – Syntocinon, Methergine and misoprostol to 50 mothers of group A, B and C respectively.
- Time interval between delivery of the baby and delivery of the placenta was noted.
- Blood collected in the BRASS-V-DRAPE was measured and recorded. Any PPH was noted and managed. Any additional uterotonics, when needed was administered.
- Pulse, temperature and BP were recorded one hour after delivery.
- Any complaint like nausea, vomiting, shivering, fever, headache and diarrhoea were noted.
- Repeat Hb estimation was done 24 hours after delivery.

Ethics
Ethical clearance was obtained from the Institutional Ethics Committee before undertaking the study.

Statistical analysis was done with Statistical Analysis Software (SPSS Version 16) using ANOVA test followed by Post hock Test, Turkey test.

X² was not done as many cells were empty which made the test invalid.

RESULTS
A total of 150 cases were studied. Demographic variables in the three groups are shown in table 1. The women in the three groups are comparable with regards to age, weeks of gestation and parity.

Events in labour are shown in table 2. Oxytocin has shortest duration of 3rd stage followed by Methergine, with misoprostol having longest duration [p value between Group A & B = 0.002, between Group B and C = 0.0001 and between Group A and C = 0.0001 statistically significant]. PPH was diagnosed in 2, 5, & 10 cases with oxytocin, Methergine, and misoprostol respectively.

Need for additional uterotonics was maximum with misoprostol having longest duration [p value between Group A & B = 0.002, between Group B and C = 0.0001 and between Group A and C = 0.0001 statistically significant]. PPH was not required in the 2 cases of Group A but was needed in one out of 5 cases of Group B and 3 out of 10 cases of Group C. Mean pre-delivery and post-delivery Hb difference in all the groups were not statistically significant. (p = 0.07).

Side effects with different oxytocics are shown in Table 3. Headache, nausea, vomiting, hypertension and pyrexia are more common with Methergine whereas shivering and diarrhoea were more common with Misoprostol. Oxytocin had least side effects of all.
DISCUSSION

Age, parity and gestational age as noted in our study is similar to other institutional studies in India. In our observation, duration of third stage of labour was the shortest with oxytocin followed by Methergine, with Misoprostol having longest duration. Oxytocin and Methergine were found equally effective in one study whilst Methergine was found more effective in another study.

However, oxytocin was found superior to Misoprostol in another study.

Regarding reduction of blood loss in the present study, Oxytocin was most effective and Misoprostol least. Observation of a study at Nepal with oxytocin and Misoprostol was similar to ours, but at a study in Himachal Pradesh, both were found equally effective. Comparison between oxytocin and Methergine was contrary to ours in the studies by Ezaemaco et al and at SSG Medical College, Gujarat. These inconsistent findings may partly be due to different other methods adopted in estimating blood loss, some are less accurate and inconsistent and many studies included induced labour.

Difference in the pre and post-delivery mean Hb was not statistically significant in the present study, similar to other studies.

Oxytocin group had least number of PPH in the present study similar to Saito et al from Japan. This is dissimilar to Gohil et al and a Nigerian study. Dissimilarity is partly due to other less accurate method of estimation of blood loss as well as due to difference in the amount of blood loss in defining PPH.

In the present study, need for blood transfusion was nil with Oxytocin, 2% with Methergrine and 6% with Misoprostol, in contrast to Gohil T.J. with 1%, 1% and 7% respectively.

Headache and hypertension, nausea, vomiting and pyrexia noted with Methergine in our study is also similar to other studies. Shivering observed with Misoprostol in our study was also the observation of Shrestha et al. Shivering and diarrhoea with Misoprostol observed in the present study was also the observation of Gohil et al.

CONCLUSION

Oxytocics used for active management of labour are useful in reducing postpartum haemorrhage, and shortening the duration of labour. Of the oxytocics, synthetic oxytocin has advantages over others in reducing blood loss and shortening duration of labour with less side effects, less need for additional uterotonics and less need for blood transfusion.
ACKNOWLEDGEMENT

We are grateful to the Principal and Medical Superintendent cum Vice Principal, Calcutta National Medical College and Hospital and West Bengal University of Health Sciences for allowing the study.
