ABSTRACT

BACKGROUND
A baby’s weight at birth is the key determinant for its survival and development. It reflects the health and nutritional status of the mother during reproductive period and particularly in pregnancy. The objective of this study is to know the proportion of low birth weight neonates and the effect of maternal age and parity on birth weight.

MATERIALS AND METHODS
A retrospective study was conducted, whereby data was obtained from the delivery records maintained at the Sonai primary health centre (PHC) from April 2016 to March 2017. Statistical Analysis Used- Chi-square test.

RESULTS
The proportion of LBW neonates was found to be 11.08%. Majority of the LBW neonates, i.e. 90.4% weigh between 1.5 and 2.5 kg. Percentage of LBW neonates was found to be highest among women less than 20 years (13.5%) of age and in multipara (26.8%).

CONCLUSION
Emphasis has to be laid on universal and early registration of pregnant women, regular antenatal check-ups and nutrition education of rural mothers.

KEYWORDS
Proportion, Low Birth Weight, Primary Health Centre, Sonai.

the new-borns were measured without clothes on a digital weighing scale soon after the birth. Birth weight of less than 2500 gm is considered as low birth weight baby. The mother’s age was taken as per case sheet record. Data was analysed using SPSS version 20 statistical software. Chi-square test was applied as a test of significance.

Ethical Consideration
Ethical clearance was obtained from the Institutional Ethics Committee of Silchar Medical College prior to commencement of the study.

Definitions
Birth Weight
Weight of the new-born should be obtained immediately after birth and ideally it should be measured within the first hour of birth before significant postnatal weight loss occurs.

Low Birth Weight
Birth weight of a new-born baby who weighs 2.5 kg or less irrespective of gestational age.

RESULTS
A total of 2238 deliveries were conducted in the hospital over a period of 12 months. The total number of live births was 2174. Maternal age ranged between 18 and 37 years. The proportion of LBW neonates was found to be 11.08%.

Table 1 shows the age distribution of pregnant women admitted to the PHC of Sonai, Cachar, Assam. The table shows that maximum number of pregnant women, i.e. 42.9% was between the age group of 25 and 29 years.

Table 2 shows the distribution of low birth weight babies in the last 12 months according to weight. Out of a total of 2174 live births, 241 (11.08%) were low birth weight and maximum number of low birth weight babies (90.4%) had birth weight between 1.5 and 2.5 kg.

Table 3 shows the association of low birth weight with maternal age. The table shows that maximum number of low birth weight babies (13.5%) was born to women in the age group of 25 and 29 years.

Table 4 shows the association of parity with low birth weight. The table shows that maximum number of primiparous mothers (26.8%) was born to women in the age group of 25 and 29 years.

DISCUSSION
Birth weight is the single most important criterion for determining the neonatal and infant’s survival. LBW is associated with high infant mortality, especially of deaths within the first month of life. Over the decades, several intervention programmes including Reproductive and Child Health and in recent years RMNCH + A (reproductive, maternal, new-born, child and adolescent health) have been launched all over India to improve the health status of mothers and children.

This study was carried out in a rural Primary Health Centre, Sonai, Cachar, Assam among 2238 number of delivered mothers to determine the prevalence and to assess some of the maternal factors associated with LBW.

In our study, proportion of LBW was found to be 11.08% which is low compared to that observed in other hospital-based studies by Lateef E et al7 (29.65%) and Rajashree K et al8 (31.3%). Joshi SM et al9 and Nayak RK et al10 found a low proportion of LBW 11.8% and 8.3% respectively. These variations could be more number of high risk deliveries in secondary and tertiary level hospitals and also better availability and utilisation of antenatal services in rural areas.

In the present study maximum number of pregnant women, i.e. 42.9% were between the age group of 25 and 29 years, similar to a study done by Ade A et al11 which may be a factor of increased age at marriage, delaying the first pregnancy or maintaining birth interval. In this study, the proportion of LBW is high in women less than 20 years of age. Similar observations were also reported by Negi et al12 and Kamalados et al.13 In the present study, majority (90.4%) of LBW babies were in the weight category of 1.5 to 2.5 kg. Similar findings were also observed in the study conducted by Lateef et al7 and Nayak RK et al10. In this study majority (26.8%) of LBW was observed amongst multipara mothers and found statistically significant, which is quite similar to observation of Nirmalya Manna et al.14 On the contrary to this, a study done by Gosavi SV et al15 observed higher proportion of LBW in primiparous mothers.

Limitation of Study
Proper antenatal care plays a crucial role in the outcome of pregnancy. Since this is a hospital-based retrospective study, we could not obtain precise information regarding quality of antenatal care, iron folic acid intake and risk status of mother.
Moreover, we could not obtain all socio-demographic data, which may have co-relation with low birth weight. As it is a hospital-based study from a single hospital, only those neonates born at the PHC were included.

CONCLUSION
In the present study, the proportion of low birth weight in Sonai PHC was 11.08%, which is lower than the national average for rural areas. Some of the factors related with low birth weight are maternal age at delivery, parity and short birth interval. It is the need of the hour to strengthen the existing maternal health services at the basic level of community, i.e. at door steps of the beneficiaries. Therefore, our study recommends improvement in early registration of antenatal mothers, universal coverage of adequate and quality antenatal care, early detection of high risk pregnancy, maternal nutrition during pregnancy, avoiding close birth spacing and delayed child bearing in young females (< 20 years).

ACKNOWLEDGEMENTS
We are thankful to Dr. NG Surendra Singh, Sonai PHC, for the permission and helping in getting the data. We thank all GNM staffs and staffs of block programme management unit, who have extended their cooperation for the study.
