PRESENTATION OF CASE
A 35-year-old female presented with firm, mandibular swelling localised in right hemi-mandible involving body and reaching up to symphysis menti. Clinically, patient was reported to the Dental Department complaining of an asymptomatic slow-growing swelling, which gradually increased to the present size within a period of 2 years’ duration in the lower right hemi-mandibular region. The onset was spontaneous and there was no history of trauma or functional impairment. Extraoral examination revealed few cervical lymph nodes of normal size and consistency. On intraoral examination the painless, firm, swelling of (6 x 7 x 8 cm) mass was located in the right hemi-mandibular body covered by a normal oral mucosa. (Fig. 1)

Digital left oblique radiograph (Figure A) showed a large expansile lesion with central crown involvement with dense calcification (white arrow) in right mandible involving body and reaching up to symphysis menti; while MDCT axial (Figure B), sagittal (Figure C) and 3D (Figure D) showing buccal and lingual cortical breech (Yellow arrow) and central crown of molar with dense calcified materials with subtle flakes appearance (red arrow) and 3rd molar tooth root erosion (Blue arrow) (Figure 2).

The decision was made to excise the lesion under general anaesthesia and histopathological evaluation.

DIFFERENTIAL DIAGNOSIS
I am aware of the diagnosis in this case. This patient is middle aged female with overall excellent health with large external expansile swelling in right lower jaw region is noted. The key finding on clinical evaluation is the lesion originating and involving right hemi-mandibular body region. The findings on imaging can be explained as mixed radiolucent radiopaque lesion, so diagnosis are Central Califying Epithelial Odontogenic Tumour (CEOT), Calcifying odontogenic cyst, Adenomatoid odontogenic tumour, Complex odontoma, Ameloblastic fibro-odontoma, Fibro-osseous lesions and osteoblastoma should be considered. A radiopaque irregular mass was seen in the centre of the tumour, which could have been a calcified mass like a complex odontoma or the crown of an impacted tooth. When associated with an unerupted/impacted tooth, the radiopacities may be seen clustering near the tooth crown with the apex perforating the cortex, which is confused with other lesions associated with impacted tooth such as dentigerous cyst, AOT (Adenomatoid Odontogenic Tumour) and the calcifying odontogenic cyst.

Clinical diagnosis
Clinically, patient had an asymptomatic slow-growing huge expansile swelling in lower right hemi-mandibular region, which gradually is increasing in size with no history of trauma or functional impairment. There are also few cervical lymph nodes of normal size and consistency noted ipsilaterally. On intraoral examination the painless, firm, swelling located in the right hemi-mandibular body covered by a normal oral mucosa. After digital radiography and MDCT evaluation, we made our first consideration of intraosseous (central) calcified epithelial odontogenic tumour (CEOT).

Figure 1
subtypes have been reported. According to the histologic classification of Ai-Ru et al.\(^4\) In the present case, type 1 histopathological findings are present.

**DISCUSSION OF MANAGEMENT**

Central Calcifying Epithelial Odontogenic Tumour (CEOT) is a rare benign tumour. Although CEOT is a benign neoplasm, its biologic behaviour is variable, ranging from very slight to moderately invasive.\(^2\) CEOT occur over a broad age range; however, they are slightly more common between 3rd and 6th decades of life.\(^5\) There is no gender predilection. In present study, single case of CEOT patient aged 35 years female was noted. About half of the cases of CEOT are associated with an impacted tooth, usually with a mandibular molar tooth.\(^6\) The treatment methods can range from simple enucleation or curettage to hemi-mandibulectomy or hemi-maxillectomy.\(^7\) Enucleation with a margin of normal tissue is usually recommended for mandibular lesions. CEOT of the maxilla should be treated more aggressively as maxillary tumours grow more rapidly and are usually not well confined. Treatment, however, should be individualized for each case.\(^7\)

As our patient had large expansile swelling of 6 x 7 x 8 cm in the right hemi-mandibular body reaching up to symphysis menti with central crown involvement and dense calcification in showing buccal and lingual cortical breech, the decision was made to excise the lesion under general anaesthesia. The patient underwent right hemi-mandibulectomy and no recurrence is reported in 6 months of followup. Long-term followup, at least 5 years, is a must as there is high risk of recurrence if the tumour was incompletely resected, especially with clear cell variant, which is locally more aggressive. The recurrence rate may range from 14% to 20%. The malignant behaviour is extremely rare.\(^8\)

**FINAL DIAGNOSIS**

Giant Central (Intraosseous) Calcifying Epithelial Odontogenic Tumour (CEOT).
