ABSTRACT

BACKGROUND
Foreign bodies in gastrointestinal tract (GIT) is clinically a serious condition with associated risks for morbidity and mortality. Commonly found objects include coins, fish bones, chicken bones, pieces of glass, dental prosthesis, batteries and needles. The goals of initial assessment are to identify the type of object and its location in the gastrointestinal tract. Plain radiographs help in the localisation of radiopaque foreign bodies and in assessing the type of foreign body. Aim of the study is to evaluate the usefulness of plain radiographs in the evaluation of foreign bodies in gastrointestinal tract.

MATERIALS AND METHODS
The study is a retrospective study of 30 cases from February 2016 to July 2016 in the age group 1 to 65 years who presented in the emergency department with the history of radiopaque foreign body ingestion or insertion. Plain radiographs were taken for the patients for assessing the location and type of foreign body.

RESULTS
Of the 30 cases, coins were the commonest foreign body ingested with 14 cases. 5 cases were fish bone ingestion, 3 cases were safety pins, 3 cases were dentures and dental wires, 2 cases were chicken bone, 1 case was pendant, 1 case was glass piece and 1 case was bathroom faucet. The foreign bodies were mostly located in the stomach (10 out of 30 cases). Retropharyngeal air was seen in one of the cases indicating perforation of pharynx by the foreign body.

CONCLUSIONS
The study concluded that plain radiographs are helpful in identifying the type of radiopaque foreign body and in the localisation of foreign body in the gastrointestinal tract. Complications of foreign body ingestion like perforation can also be diagnosed in plain radiographs. The study also concluded that plain radiographs are useful in following the foreign body in gastrointestinal tract and also in giving a road map to the surgeons for the management of the foreign body in the gastrointestinal tract.

KEYWORDS
Foreign Body, Radiopaque, Gastrointestinal Tract, Localisation.

BACKGROUND
Foreign bodies in gastrointestinal tract (GIT) is clinically a serious condition with associated risks for morbidity and mortality. Almost 80% of cases are in early childhood (2 to 4 years) with majority of cases resulting from swallowing coins. Commonly found objects include coins, fish bones, chicken bones, pieces of glass, dental prosthesis, batteries and needles. The ingestion of foreign bodies in adults is accidental and is commonly fish or chicken bone ingestion. Almost 80 to 90% of foreign bodies pass freely from GIT without any complication. 10 to 20% will require endoscopic removal and only 1% will require surgery. The goals of initial assessment are to identify the type of object and its location in the gastrointestinal tract. Plain radiograph helps in the localisation of foreign body and in assessing the type of foreign body.

AIM OF THE STUDY
Aim of the study is to evaluate the usefulness of plain radiographs in the diagnosis and localisation of foreign bodies in the gastrointestinal tract. The study is also used to assess the types of foreign body ingested or inserted into the gastrointestinal tract.

MATERIALS AND METHODS
The study is a retrospective study of 30 cases between February 2016 to July 2016 in the age group 1 to 65 years who presented in the emergency department with history of accidental radiopaque foreign body ingestion or insertion. Out of the 30 cases, 14 were male and 16 were female patients. Plain radiographs were taken for all patients for assessing the location and type of foreign body. Both AP and lateral views are necessary as some radiopaque foreign bodies overlying vertebral column may be visible only in lateral view. The radiographs taken are plain radiographs of neck, chest and abdomen.

RESULTS
Of the 30 cases, coins were the commonest foreign bodies ingested with 14 cases. 5 cases were fish bone ingestion, 3 cases were safety pins, 3 cases were dentures and dental wires, 2 cases were chicken bone, 1 case was pendant, 1 case was glass piece and 1 case was bathroom faucet (Table 1).
The foreign bodies were mostly located in the stomach (10 out of 30 cases), 2 foreign bodies were located in nasopharynx, 7 foreign bodies were located in oropharynx, 6 foreign bodies were in the oesophagus, 4 foreign bodies were in the colon and 1 the rectum (Table 2).

**Table 2: Location of Foreign Bodies (n=100)**

With this initial information, the cases were followed with serial radiographs. 25 out of the 30 foreign bodies passed out of the gastrointestinal tract spontaneously. 4 cases of fish bone located in oropharynx required endoscopic removal. The case of accidental insertion of faucet into the rectum required surgical intervention as two-staged procedure. The faucet has perforated the rectum and emergency colostomy was done for the patient to allow the rectal perforation to heal. Revision and closure of the colostomy was done at a later date.
Serial radiographs are used to determine the passage of the foreign body and the complications resulting from it. Foreign bodies in GIT are usually treated conservatively. Almost 80 to 90% of foreign bodies pass freely from GIT without any complication. 10 to 20% will require endoscopic removal[3] and 1% will require surgery.

The most common complication of foreign body ingestion is perforation. Retropharyngeal air (Figure 8), pneumomediastinum and pneumoperitoneum are seen in plain radiographs in cases of foreign body perforation of the GIT.(4,5,6) In cases of perforation of GIT by foreign body management is by emergency surgery. In our study, there was no mortality.

CT scan may be done in cases where plain radiographs are inconclusive.(7,8)

CONCLUSION

Plain radiographs are helpful in identifying the type of radiopaque foreign body and in the localisation of foreign body in the gastrointestinal tract. Complications of foreign body ingestion like perforation can also be diagnosed in plain radiographs. The study also concluded that plain radiographs are useful in following the foreign body in gastrointestinal tract and also in giving a road map to the surgeons for the management of foreign body in the gastrointestinal tract.

ACKNOWLEDGEMENTS

The authors would like to thank Mr. Mariappan for his contribution in images and data collection.
