²Assistant Professor, Department of General Medicine, SIMS, Shimoga.

ABSTRACT

BACKGROUND
Dengue is a major health concern, especially in tropical country like India. Hepatic dysfunction in dengue fever is a common feature which complicates the clinical course of the infection and worsen the prognosis. This study was done to assess the frequency and spectrum of liver dysfunction in Dengue infection patients.

MATERIALS AND METHODS
It was a prospective observational study done in Vaatsalya Hospital, Shimoga, for the duration of 6 months, i.e. from 16/05/2017 to 15/11/2017. All patients attending Vaatsalya Hospital, Shimoga with positive serological tests were included in the study after taking written informed consent. Complete blood count and LFT were done and severity of hepatic dysfunction was based on the extent to which ALT and AST were elevated.

RESULTS
100% of patients had elevated AST, 100% patients had elevated AST and 85% patients had elevated ALT. The albumin level was low in 75% patients. Average AST was 31.6 units/L and average ALT was 15.6 units/L.

CONCLUSION
Hepatic involvement in dengue is universal. AST elevation is more common than ALT elevation. Reversal of AST to ALT ratio along with high-grade fever and constitutional symptoms may help in early diagnosis of dengue.

KEYWORDS
Dengue Fever, Hepatic Dysfunction, AST, ALT, Thrombocytopenia.

BACKGROUND
Dengue infection is an arthropod-borne viral infection caused by flavivirus and transmitted by Aedes Aegypti mosquito.¹ It is the second most common cause of vector-borne febrile illness next to malaria and in the recent years number of cases were reported to have drastically increased and it has become a major public health issue.² According to WHO estimation, presently about two-fifths of the world population is at risk for this viral infection.³ Patients present with various symptoms which include high-grade fever, chills, backache, arthralgia, myalgia, headache, abdominal pain, vomiting, sore throat, conjunctival congestion, maculopapular rashes and petechiae. Depending on the severity of symptoms it can be classified into dengue fever, dengue haemorrhagic fever and dengue shock syndrome. In almost all cases of dengue, liver is affected in variable severity ranging from asymptomatic raise of liver enzymes to acute fulminant hepatitis. However, there are only few prospective studies which has documented hepatic involvement and degree of hepatic injury in dengue fever. Hence, in our study we aim to assess the hepatic involvement and degree of hepatic injury in dengue fever.

Review of Literature
Gandhi K and M Shetty evaluated 53 patients with dengue fever in KMC Mangalore, out of which 27 patients were serologically positive and found that 85% of patients had at least one of the aminotransferases high. AST elevation was raising quickly and was peaking higher than ALT.⁴

S Fernando et al evaluated 55 adult patients with dengue fever. These patients were subjected for serial monitoring of liver function tests, viral loads and found that AST, ALT and GGT were raised in all patients and peak level was found on 6th day.⁵

Itha S et al evaluated 45 patients with dengue fever which included 23 uncomplicated dengue fever with 15 dengue haemorrhagic fever and 7 with dengue shock syndrome. In their study seven patients (15%) had jaundice, 11 (24%) had hepatomegaly and 9 had clinically detectable ascites. ALT and AST were elevated in 96% of patients and there was no specific raise of one enzyme and magnitude of elevation of both enzymes were comparable. 76% of patients had hypoalbuminemia.⁶

Vaibhav Shukla and Ashok Chandra evaluated patients with dengue fever. In their study 100% patients had an elevated SGOT level, while 91% patients had elevated SGPT level. 85% of patients had their SGOT level more than two times of the normal range, while 48% patients had SGPT levels more than two times of the normal range. Inpatients with both aminotransferase raised, the SGOT levels were 2-3 times higher than SGPT levels. 50% of patients had hepatomegaly.⁷
Aims and Objectives
To study hepatic function derangement in dengue fever.

MATERIALS AND METHODS
It is a prospective observational study done in Vaatsalya Hospital, Shimoga for the duration of 6 months, i.e. from 16/05/2017 to 15/11/2017. All patients attending Vaatsalya Hospital, Shimoga with history of high-grade fever for minimum of 3 days’ duration with constitutional symptoms were subjected for complete blood count test, LFT and dengue antigen and serological test. Patients with positive serological test were included in the study after taking written informed consent. Patients younger than 15 years and older than 70 years and patients with history of hepatitis, alcoholics, history of pre-existing liver disease were excluded from the study. Severity of hepatic dysfunction was based on the extent to which ALT and AST were elevated and were classified into four groups. It was considered normal when AST and ALT were 40 U/L. Patients with normal values were assigned Group 1, patients with elevated ALT or AST or both but less than three times the normal range were assigned Group 2. Patients with raised ALT or AST or both more than three times the normal range, but less than ten times were assigned Group 3. Patients with raised ALT or AST or both more than ten times the normal range were assigned Group 4.

RESULTS
60 patients were included in the study, out of which 40 (66.6%) were males and 20 (33.3%) were females. Mean age of presentation was 36 years, most of them were in the age group of 15 to 45 years. 27 (45%) patients had clinically enlarged liver, 16 (26.6%) had leukopenia. 4 (6.6%) patients found to be 42000 and 6 (10%) patients had platelet count less than 100000. Average total bilirubin was 3.57 mg/dL and direct bilirubin was 1.34 mg/dL. Average albumin level was 3.98 g/dL and globulin level was 2.23 g/dL. Average AST was 316 units/L and average ALT was 420 units/L. Patients with raised ALT or AST or both more than ten times the normal range were assigned Group 4.

In our study 27 (45%) patients were under Group 2; 5 (41.6%) patients were under Group 3; and 8 (13.3%) patients were classified under Group 4.

Table 1. Liver Function Profile in Our Study Group

DISCUSSION
In our study, all patients had hepatic involvement in various degree. Hepatic dysfunction in paediatric cases are well documented.8,9,10 There are only few prospective studies documenting hepatic dysfunction in dengue. Our study results were similar to previous studies.4,11,12 Most of them had mild-to-moderate dysfunction with few acute hepatitis. None had fulminant hepatitis or dengue shock syndrome.

In our study, all patients had raised AST either alone or along with raised ALT and in cases where both AST and ALT were raised AST was much higher in comparison with levels of ALT. This pattern is usually noticed in alcoholic liver disease. This result is comparable to other studies.5,7 This reversal of AST and ALT is not seen in other forms of viral hepatitis. In a study by Itha S et al,6 though there was elevation of hepatic enzymes there was no preferential raise in one enzyme which is in contrast to our study result.

CONCLUSION
In dengue patients, liver involvement is almost universal. There was no relationship between severity of dengue and severity of dengue fever. But elevation of liver enzymes, specifically reversal of AST and ALT ratio along with high-grade fever and other constitutional symptoms suggesting dengue fever may help in diagnosis of dengue in early cases where serological test is not positive and to differentiate it from other infections mimicking dengue clinically.

ACKNOWLEDGEMENTS
Authors acknowledge the immense co-operation received by the patients and the help received from the scholars whose articles are included and cited in reference to this manuscript. The authors are also grateful to authors/editors/publishers of all those articles, journals and books from where the literature for this article has been reviewed and discussed.
