A CASE REPORT OF CORNEAL TUNNEL ABSCESS FOLLOWING ND-YAG LASER CAPSULOTOMY

Syed Heena Kubravi, Syed Tariq Qureshi, Khalid Kawoosa

PRESENTATION OF THE CASE
We describe the case report of a patient who developed a corneal abscess following Nd:YAG laser treatment.

History
A 55-year-old woman, nondiabetic, non-hypertensive presented to eye OPD with complaints of pain, redness, watering and diminution of vision in right eye since 5 days.

There was a history of cataract extraction (phacoemulsification with PCIOL implantation) in right eye 45 days back followed by Nd:YAG laser capsulotomy 5 days back in the same eye. Post laser, patient developed redness associated with watering, discharge and pain with decreased vision. Patient had been using topical antibiotic steroid drops for 2 weeks following cataract surgery.

Ocular Examination
The visual acuity in right eye was finger counting up to 2 mts. The extraocular movements were normal. Lids were oedematous while conjunctiva was congested. Corneal examination showed a tunnel abscess at 12 o’clock extending to 9 o’clock 4 mm x 4 mm surrounded by dense infiltrate and corneal oedema.

DIFFERENTIAL DIAGNOSES
1. Corneal ulcer.
2. Corneal abscess.
3. Endophthalmitis.

CLINICAL DIAGNOSIS
Corneal tunnel abscess.

Management
Topical medication was stopped for 24 hrs. and corneal scrapings were taken. Gram staining and KOH staining was done. KOH staining was negative while Gram stain revealed gram-positive cocci. Culture was done using blood agar, which revealed pneumococci.

Treatment
Topical fortified cefazolin 5% e/d and topical fortified tobramycin 1.3% e/d were prescribed 1 hrly. for 48 hrs. t/b 2 hrly. during day and 4 hrly. at night for 7 days, then 6 hrly. for 2 weeks. Atropine 1% e/d t.i.d. and lubricating eye drops 2 hrly. were added. Treatment was continued for 1 month following which patient improved symptomatically.

DISCUSSION OF MANAGEMENT
Photodisruption with neodymium-doped yttrium aluminium garnet (Nd:YAG) laser has been used to treat a number of complications arising after cataract surgery and IOL implantation. The optical breakdown of the laser pulse creates a pressure wave, which allows the surgeon to cut and manipulate various intraocular structures. It has been seen that Posterior Capsular Opacification (PCO) is one of the commonest complications of cataract surgery. Although, Nd:YAG laser is a safe and noninvasive technique for PCO, it is not without complications, some of which can be sight threatening. The technique of incision in cataract surgery has evolved from the conventional, large 12 mm wound closed with multiple sutures to small incision sclera tunnel and now to clear corneal tunnel incision. This incision used in phacoemulsification allows faster postoperative recovery and visual rehabilitation with minimum discomfort and less incidence of postoperative astigmatism. However, it has also been associated with an increased incidence of postoperative infections ranging from mild keratitis to endophthalmitis, which can result in severe loss of vision.

Nd:YAG laser is now a standard procedure for treating secondary opacification of posterior capsule and contraction of anterior capsule following cataract surgery. This is a simple procedure in most cases, but is not without risks. Complications include IOL damage, IOL subluxation or dislocation, retinal detachment and secondary glaucoma. Corneal tunnel abscess, though rare, can occur as a complication following laser capsulotomy. Delayed postoperative endophthalmitis may also be rarely

precipitated by Nd:YAG laser capsulotomy, which releases organisms into vitreous.\textsuperscript{4,5,6,7,8}

The most common organisms isolated in corneal abscesses include Staphylococcus aureus, Staphylococcus epidermidis and Pneumococcus. The commonest sources of these organisms seem to be the normal flora of the eyelids or conjunctiva. Prolonged use of antibiotics and steroids following the surgery maybe an additional risk factor as it may result in selection of more virulent forms, which can invade the cornea.\textsuperscript{9,10,11,12}

This case report illustrates the importance of extended followup following laser capsulotomy. Understanding the risk factors for development of postoperative infections is also crucial in prevention and management of such conditions. Proper preoperative preparation, use of sterile instruments, sterile operative technique and meticulous wound construction and closure during surgery can reduce the incidence of infections. In patients who develop infectious complications, urgent recognition and prompt referral is critical to optimal outcomes.

**FINAL DIAGNOSIS**
Corneal tunnel abscess following Nd:YAG laser capsulotomy.
