**ABSTRACT**

**BACKGROUND**

Numerous attempts have been made in the past to attenuate the pressor response that arises from the manipulation of the airway, attributed to the sympathoadrenal discharge because of stimulation of epipharyngeal and parapharyngeal regions. This study compares the effects of two synthetic opioids Fentanyl and Butorphanol in attenuating the pressor response to laryngoscopy and intubation.

The aim of this study is to compare the pressor response to laryngoscopy and intubation using intravenous Fentanyl and Butorphanol on the following parameters: (1) Heart Rate, (2) Systolic BP, (3) Diastolic BP, (4) Mean Arterial Pressure and (5) Rate Pressure Product.

**MATERIALS AND METHODS**

This study is a double-blind randomised trial comparing two opioid drugs, Fentanyl and Butorphanol; it was carried out at the Department of Anaesthesiology, Chengalpattu Medical College, Tamilnadu. With the Institutional Ethical Committee approval, 60 ASA PS I patients of either sex of age between 20 and 50 years scheduled for elective surgeries under general anaesthesia were enrolled into two groups, Group B - Inj. Butorphanol 40 µg/kg IV and Group F - Inj. Fentanyl 2 µg/kg IV administered 5 minutes before Laryngoscopy and Intubation. Haemodynamic parameters were recorded for up to 10 minutes after endotracheal intubation.

Statistical Analysis - The results were systematically analysed using paired "t" test for variables within the group and unpaired "t" test for variables between the two study groups. Software used for analysis of data was SPSS for windows. P value of less than 0.05 was considered statistically significant.

**RESULTS**

We observed that the rise in haemodynamic parameters following laryngoscopy and intubation was significantly lower in the Butorphanol group when compared to the Fentanyl group. The parameters like HR, Diastolic BP, mean arterial pressure and rate pressure product were short-lived in the Butorphanol group.

**CONCLUSION**

Butorphanol has a significant advantage over an equipotent dose of fentanyl in the sense that the increase in the stress response was comparatively less and of shorter duration.

**KEYWORDS**

Fentanyl, Butorphanol, Laryngoscopy, Intubation.

**BACKGROUND**

In spite of several new airway devices emerging in recent times, direct laryngoscopy and endotracheal intubation still reigns as the gold standard in airway management.

Laryngoscopy and intubation of the tracheal tube are noxious stimuli and changes in haemodynamics are attributed to the stimulation of epipharyngeal and parapharyngeal region. These changes are manifested as rise in heart rate and blood pressure which are variable, transient and unpredictable.

Although, a normotensive patient can tolerate this response, it may pose serious challenges in hypertension, coronary artery disease that intracranial compliance like extra- or intra-dural haematoma tumours or aneurysms, left ventricular failure, myocardial ischaemia and cerebral haemorrhage can be precipitated by sudden changes in haemodynamics.

Some pharmacological agents used to suppress the pressor response are volatile anaesthetic agents¹ - lignocaine,² opioids,³ vasodilators (Sodium nitroprusside,⁴ nitroglycerine,⁵ calcium channel blockers⁶ and adrenergic blockers⁷). The non-pharmacological methods include smooth and gentle intubation with a shorter duration of laryngoscopy, use of LMA⁸ and blocking glossopharyngeal and superior laryngeal nerves.⁹
Opioids have been employed for this purpose for quite some time and has been proved extremely useful in attenuating the pressor response apart from providing good analgesia.

Hence, in this study we have decided to compare the effects of two opioids, fentanyl and Butorphanol, in attenuating the pressor response to laryngoscopy and intubation.

Fentanyl\textsuperscript{10} is a phenyl piperidine derivative synthetic opioid agonist that is structurally related to meperidine. As an analgesic, fentanyl is 75 to 125 times more potent than morphine. A single dose of fentanyl administered intravenously has a more rapid onset and shorter duration of action than morphine. Low doses of fentanyl, 1 to 2 $\mu$g/kg IV, are injected to provide analgesia. Fentanyl, 2 to 20 $\mu$g/kg IV, may be administered as an adjuvant to inhaled anaesthetics in an attempt to blunt circulatory responses to direct laryngoscopy for intubation of the trachea. A unique aspect of fentanyl's clinical application is that it can be delivered in numerous ways. In addition to the intravenous route, transdermal, transmucosal, transnasal and transpulmonary routes can also deliver fentanyl.

Butorphanol is an agonist-antagonist opioid, an agonist at K-receptors. Its activity at $\mu$-receptors is either antagonistic or partially agonistic. It is five to eight times as potent as morphine and is available only in parenteral form, whereas the duration of action of butorphanol is similar to that of morphine, its plasma half-life is only 2 to 3 hours. Side effects after butorphanol include drowsiness, sweating, nausea and CNS stimulation.

**Aims and Objectives**

To compare the attenuation of pressure response to laryngoscopy and intubation with fentanyl and butorphanol using the following parameters.

1. Systolic BP.
2. Diastolic BP.
3. Mean arterial pressure.
4. Mean pulse rate.
5. Rate pressure product.

**MATERIALS AND METHODS**

This is a double-blind randomised trial study comparing the two opioids, fentanyl and butorphanol, was carried out in Govt. Chengalpattu Medical College Hospital, Tamilnadu, after obtaining the Institutional Ethical Committee approval and written informed consent from the patients.

Sixty patients were randomly subjected to this study. Thirty patients were enrolled into Group F and thirty patients were enrolled into Group B.

**Inclusion Criteria**

1. ASA PS I.
2. 20 - 50 years of age.
3. Both sex.
4. Elective procedure under GA.
5. Mallampati airway class I and II.

**Exclusion Criteria**

1. Hypertension.
2. Valvular heart disease.
3. Ischaemic heart disease.
4. Endocrine disorders.

5. Metabolic disorders.
6. Respiratory disease.
7. Anaemia.
8. Allergic diathesis.

The two drugs fentanyl and butorphanol were compared in their efficiency in attenuating the pressor response to laryngoscopy and endotracheal intubation in terms of their effect on heart rate, systolic BP, diastolic BP, mean arterial pressure, rate pressure product.

All patients were examined preoperatively and assessed with history, physical examination and necessary laboratory investigations. Patients were randomly divided into two groups: Group B (Butorphanol) and Group F (Fentanyl).

On the day of surgery, all patients were reassessed in the patient's waiting room. Heart rate, systolic BP, diastolic BP and mean arterial pressure were recorded and noted as the first preoperative value (Pre-Op 1). All patients received Inj. Glycopyrrolate 0.005 mg/kg and Inj. Midazolam 0.05 mg/kg intramuscularly as premedication. Thirty minutes later the patients were shifted inside the operating room. Heart rate, systolic BP, diastolic BP, mean arterial pressure were recorded and noted as second preoperative value (Pre-Op 2). This was taken as the baseline value for comparison of different parameters at various time intervals. After recording the baseline parameters, patients in Group F received Inj. Fentanyl 2 $\mu$g/kg and Group B received Inj. Butorphanol 40 $\mu$g/kg by intravenous route. Heart rate, systolic BP, diastolic BP and mean arterial pressure were recorded for 5 minutes and the fifth minute values were noted as the Pre-Induction values (PI). Occurrence of any haemodynamic variability was noted down, i.e. greater than 20% decrease in mean arterial pressure was defined as hypotension and less than 60 beats per minute was defined as bradycardia when compared to preoperative values (Pre-Op 2).

Five minutes after the administration of the test drug, patients were pre-oxygenated with 100% oxygen and induced with Inj. Thiopentone sodium 5 mg/kg IV as 2.5% solution. Inj. Vecuronium 0.1 mg/kg was given to achieve muscle relaxation and controlled positive pressure ventilation was done with 100% oxygen by mask. After 3 minutes, endotracheal intubation was done with a proper sized endotracheal tube using the laryngoscope with Macintosh blade. Patients who strained more than 15 seconds of laryngoscopy and patients requiring a second attempt of laryngoscopy were excluded from the study.

Heart rate, BP (systolic, diastolic, mean arterial pressure) were recorded at the first, second, third, fourth, fifth and tenth minute following intubation and was noted as T1, T2, T3, T4, T5 and T10 respectively. No surgical stimulation was allowed for the first 10 minutes after intubation.

**Statistical Analysis**

The results were systematically analysed using paired "t" test for variables within the group and unpaired "t" test for variables between the two study groups. Software used for analysis of data was SPSS for windows. P value of less than 0.05 was considered statistically significant.

**RESULTS**

Sixty patients were subjected to this study. Thirty patients were enrolled into Group F and thirty patients were enrolled...
into Group B. There was no statistical difference between the two groups in respect to age, sex, weight and Mallampati Classification (MPC). The comparison of preoperative parameters like pulse rate, systolic BP, diastolic BP, mean arterial pressure showed no statistical difference between the two groups.

Comparison of the preoperative parameters before the premedication (Pre-Op 1) and the parameters after the premedication (Pre-Op 2) showed that there was no statistically significant difference between the two groups.

The mean heart rate is significantly lower in Group B when compared to Group F from the second and up to the tenth minute after intubation. The heart rate in Group B after intubation becomes comparable to the preoperative (Pre-Op 2) heart rate at the third minute after intubation and it becomes significantly lower than the preoperative heart rate from the fourth minute after intubation onwards. The heart rate in Group F after intubation becomes comparable to the preoperative (Pre-Op 2) heart rate at the fifth minute after intubation and it becomes significantly lower than the preoperative heart rate at the tenth minute after intubation onwards.

**Table 6. Mean MAP**

The Rate Pressure Product is significantly lower in Group B when compared to Group F from the second minute after intubation. The Rate Pressure Product in Group B after intubation becomes comparable to the preoperative Rate Pressure Product at the fourth minute after intubation and it becomes significantly lower than the preoperative Rate Pressure Product from the fifth minute after intubation. The rate pressure product in Group F after intubation becomes comparable to the preoperative Rate Pressure Product at the fifth minute after intubation and it becomes significantly lower than the preoperative Rate Pressure Product at the tenth minute after intubation.

**Table 5. Mean Diastolic Blood Pressure**

**Table 7. Rate Pressure Product**

The complications noted in a few patients of both groups were hypotension, bradycardia, shivering, nausea and vomiting. The incidence of shivering was significantly less in butorphanol group than the fentanyl group.

**Table 8. Complications**

**DISCUSSION**

Even in well-anaesthetised individuals, reflex tachycardia and hypertension on laryngoscopy and intubation occurs quite frequently. Many different opioid combinations and dosages have been tried in the past on obtunding this pressor response. In our study, we have compared IV Fentanyl and IV Butorphanol with 30 patients of each group.

King et al (1951) observed a transient but marked increase in systolic and diastolic BP during laryngoscopy. Similarly, in our study also a short duration of increase of these parameters were noted but significantly elevated BP when compared to the baseline values. We also observed a significant increase in mean arterial pressure with laryngoscopy compared to the preoperative values in both the study groups. Corbett and Kerr (1969) and Forbes and Dalhy (1970) had also observed similar changes that regressed gradually.

When heart rate following intubation was recorded at various time intervals between fentanyl and butorphanol group, the increase in heart rate in butorphanol group was
significantly lower than the fentanyl group. This was similar to the observations made by Philip BK et al\(^\text{16}\) in their study.

We recorded an increase in both systolic and diastolic BP in both groups following intubation. The increase in systolic BP was significantly lower in Group B when compared to Group F, but only for short duration during the second and third minute after intubation. During the rest of the study period, it was comparable between the two groups. In contrast, Group B showed a significant lowering of the diastolic BP from the time prior to induction to the end if the study period of ten minutes. Nevertheless, an increase was observed in both the groups following intubation. Philip BK et al and Vikramjeet Arora et al\(^\text{17}\) also observed this in their respective studies.

Yushi et al\(^\text{18}\) in his study concluded that 2 µg/kg fentanyl suppresses the haemodynamic response to endotracheal intubation more than the response to laryngoscopy.

Devavrat Vaishnav et al\(^\text{19}\) (2016) concluded that in patients with ASA Grade I and II, intravenous bolus dose of Esmolol (2 mg/kg) and Fentanyl (2 mcg/kg) given 3 minutes prior to laryngoscopy and intubation is safe and effective prophylactic method for attenuating haemodynamic response to laryngoscopy and intubation.

Jasleen Kaur et al\(^\text{20}\) (2013) concluded that butorphanol 20 µg/kg reduces the induction requirement of propofol comparable to that of fentanyl 2 µg/kg and confers haemodynamic stability at induction and intubation.

Hemangini et al\(^\text{21}\) (2016) concluded that Butorphanol 20 µg/kg gives better attenuation of the haemodynamic response, longer duration of postoperative pain relief without producing excessive sedation and with negligible side effects in comparison with fentanyl 1 µg/kg when given intravenously as premedicant for general anaesthesia.

Mean arterial pressure is a derived value and is important for the maintenance of autoregulatory function of the vital organs. Rate pressure product (HR x SBP) is a measure of myocardial oxygen demand. Both Mean Arterial Pressure and Rate Pressure Product increased in both the groups on intubation and the increase was significantly lower in the butorphanol group compared to the fentanyl group.

Both the drugs provided stable haemodynamics throughout the intraoperative period, which was also observed in Philip BK et al study.

In our study, we observed that at the doses at which the study drugs were used both could prevent haemodynamic response to a certain extent. However, butorphanol had a significant advantage over an equipotent dose of fentanyl in the sense that the increase in the stress response was comparatively less and of shorter duration.

**Summary**

We observed that there was a significant rise in heart rate, systolic BP, diastolic BP, mean arterial pressure and rate pressure product when compared to preoperative values in both fentanyl and butorphanol group following laryngoscopy and intubation.

We also observed that the haemodynamic response following laryngoscopy and intubation was significantly lower in the butorphanol group than in the fentanyl group.

The increase in the heart rate, diastolic BP, mean arterial pressure and rate pressure product was short-lived in the butorphanol group than the fentanyl group.

**CONCLUSION**

With this study we conclude that the administration of intravenous butorphanol prior to induction of anaesthesia helps on better attenuation of the haemodynamic response to laryngoscopy and endotracheal intubation than intravenous fentanyl. Neither of the drugs was associated with any adverse haemodynamic events. Hence, we conclude that butorphanol could be an effective alternative to fentanyl for the attenuation of the haemodynamic stress response to laryngoscopy and endotracheal intubation.

**Acknowledgement**

We are very grateful to the Professors and Assistant Professors of the Department of General Surgery.

We are extremely thankful to the Assistant Professors and the Postgraduates of the Department of Anaesthesiology for their help in carrying out this study.

We are thankful to the Institutional Ethical Committee for their guidance and approval for this study. Last but not the least, we thank all our patients for willingly submitting themselves for this study.

We also wish to state that no financial or material support were obtained for this study.
