ABSTRACT

BACKGROUND
Abnormal uterine bleeding can be defined as any bleeding from the genital tract, which is a deviation from the normal in frequency, cyclicity or quantity. The differential diagnosis of abnormal uterine bleeding includes organic causes that may be subdivided into reproductive tract disease, iatrogenic causes and systemic disease. Thyroid dysfunction is one of the causes included in the systemic diseases.

This study was done to know the prevalence of thyroid dysfunction in women presenting with abnormal uterine bleeding.

MATERIALS AND METHODS
227 women attending gynaeology outpatient department in Government Medical College, Thrissur, with abnormal uterine bleeding in pubertal to pre-menopausal age group were included in this study after excluding structural and endometrial pathology by clinical examination, ultrasound and endometrial sampling. These women were tested for their thyroid function by FT3, FT4 and TSH estimation in the serum. Patients who were on hormonal treatment, intrauterine contraceptive device users and had bleeding disorders were excluded from the study. Pattern of bleeding was also assessed in the study population. Patients diagnosed with thyroid dysfunction were treated and followed up for the response.

RESULTS
Out of the 227 patients, the majority of the study population belonged to the age group of 41 - 50 years (43.6%); 21.9% of the study population showed thyroid dysfunction. Of this 19.7% had hypothyroidism, out of which 12.3% were subclinical hypothyroid and 7.5% were overt hypothyroid; about 2.2% were hyperthyroid. Majority of the hypothyroid patients had menorrhagia and majority of the hyperthyroid patients had oligomenorrhoea.

CONCLUSION
Thyroid hormones play a vital role in menstrual bleeding. Identifying and correction of the thyroid status has shown to improve the symptoms in women presenting with heavy menstrual bleeding and improve the quality of life.

KEYWORDS
Abnormal Uterine Bleeding, Thyroid Dysfunction, Hypothyroidism, Hyperthyroidism, Menorrhagia, Menstrual Disorders, Subclinical Hypothyroidism.

BACKGROUND
Abnormal uterine bleeding can be defined as any bleeding from the genital tract, which is a deviation from the normal in frequency, cyclicity or quantity. It accounts for 30% - 40% of the cases in the outpatient clinic.

The causes of abnormal uterine bleeding include a wide spectrum of diseases of the reproductive system and non-gynaecologic causes as well.1 Endocrine cause is one of the important cause for abnormal uterine bleeding in the reproductive age group.2 Among the endocrine causes after the pituitary, thyroid is probably the most important.3 Both hypothyroidism and hyperthyroidism may be associated with abnormal bleeding.

Thyroid deficiency causes a change in the rhythm of the oestrous cycle resulting in lengthening or irregularity.4 Oligomenorrhoea and menorrhagia are the most frequently seen menstrual disturbances in hypothyroidism. The menorrhagia is probably the result of breakthrough bleeding associated with anovulation, which leads to deficient LH and excess oestrogen.5 Defects in clotting factors (such as decreased levels of factors VII, VIII, IX and XI) that occur in hypothyroidism may also contribute to polymenorrhoea and menorrhagia. Hyperthyroidism can result in oligomenorrhoea or amenorrhoea.6 Biochemical and hormonal abnormalities, nutritional disturbances and emotional upheavals that are commonly associated with hyperthyroidism may, individually or in combination, be the cause of the menstrual disturbances.

Replacement with synthetic levothyroxine (LT4) is the mainstay of therapy and provided that there is an intact hypothalamic-pituitary-thyroid axis. The menorrhagia associated with hypothyroidism responds promptly to thyroid replacement, as thyroxine has a direct effect on the spiral arterioles and on haemostasis at menstruation.6 Thus, estimation of thyroid hormones in serum in woman presenting with abnormal uterine bleeding and adequate
treatment after diagnosis can prevent unnecessary surgical interventions.

This study was conducted to find out the prevalence of thyroid dysfunction in women with abnormal uterine bleeding in the reproductive age group, so that by adequate treatment of the thyroid dysfunction there can be improvement in the quality of life.

MATERIALS AND METHODS

The present study has been carried out at Obstetrics and Gynaecology outpatient department of Government Medical College, Thrissur. The study is a descriptive study and was carried out after IRB approval and consent from the patient. The study consisted of 227 patients in the reproductive age group coming to OPD with complaints of abnormal uterine bleeding from February 2014 to January 2015. Woman with structural pathology, endometrial pathologies, chronic liver disease, bleeding disorders, and IUCD users on drugs like anticoagulants and antidepressants and with carcinoma thyroid were excluded from the study.

Procedure

The patients coming to Gynaecology OPD with complaints of abnormal uterine bleeding were given the proforma. A detailed history was obtained with special relevance to age and bleeding pattern. A thorough clinical examination including general physical examination with special reference to thyroid dysfunction, neck examination, gynaecological and systemic examination was carried out.

All these patients were subjected to routine investigations like haemoglobin percentage, blood counts, urine examination, prothrombin time (to rule out coagulation defects), peripheral smear and random blood sugar levels. Cervical smears were taken and transabdominal/transvaginal ultrasound was done to rule out pelvic pathology. Then all patients were subjected for Free Triiodothyronine levels (FT3), Free Thyroxine levels (FT4) and TSH estimation in their sera.

Patients were then Grouped into 4 Categories

- Euthyroid.
- Subclinical hypothyroid - where TSH is increased and FT3, FT4 is normal.
- Overt Hypothyroid - where TSH is high, FT3 and FT4 decreased.
- Hyperthyroid.

Patients found to have thyroid dysfunction were accordingly treated and reassessed for improvement in symptoms. As a part of the investigation, fractional curettage was also done and the patient was accordingly treated.

RESULTS

The above table shows that the majority of the study population belong to the age group of 41 - 50 years (43.6%). The cases of puberty menorrhagia constitute about 4.4% of the study population.

Table 2. Distribution according to Parity

In this study population, parity of the patients ranged from nulliparous to parity 3 or more. Majority of the patients belonged to para 2 (43.2%).

Menorrhagia was the most common symptom in 127 patients (55.9%), followed by acyclical bleeding in 45 patients (19.8%) and polymenorrhea in 20 patients (8.8%).

Out of 227 patients 45 (19.7%) had hypothyroidism, out of which 28 (12.3%) were subclinical hypothyroid and 17 (7.5%) were overt hypothyroid; about 5 (2.2%) were hyperthyroid.
Among the euthyroid patients also, menorrhagia is most common. In patients with hypothyroidism, majority that is 35 out of 45 had menorrhagia. Next most common was acyclical bleeding. In patients with hyperthyroidism, majority that is 3 out of 2 had oligomenorrhoea and the next most common was hypomenorrhoea.

Majority of the hypothyroid patients, that is 28 out of 45 had proliferative endometrium as the histological diagnosis on doing fractional curettage. Among the hyperthyroid patients, 3 out of 5 had proliferative endometrium. P value of this particular association was found to be 0.001, which was statistically significant.

Among the euthyroid patients, majority were given tranexamic acid alone.

Among the hypothyroid patients, majority were given tranexamic acid and thyroxine, and among hyperthyroid patients majority were given propylthiouracil.

**DISCUSSION**

Abnormal uterine bleeding is one of the most common gynaecologic problems that health care providers face, accounting for approximately 15% - 20% of office visits and 25% of gynaecologic operations. It has been estimated that a woman has 1 in 20 lifetime chance of consulting her primary physician because of menorrhagia. It has a direct impact on women’s quality of life. Both hypothyroidism and hyperthyroidism may be associated with abnormal bleeding.
polymenorrhoea. In the study by Charusheela et al, majority of hypothyroid patients had menorrhagia.

In the study by N. Sharma et al, proliferative endometrium was seen in majority of the hypothyroid and hyperthyroid patients just like in the present study.

In the present study, majority of the overt hypothyroid patients who were treated with tranexamic acid and thyroxine were successful, which was very similar to the study carried out by Wilansky et al. Wilansky tested for thyroid releasing hormone in 67 women with menorrhagia. Of these, eight had been treated with thyroxine for an abnormal test result for thyroid releasing hormone and all considered their menstrual loss to have returned to normal.

The menorrhagia associated with hypothyroidism responds promptly to thyroid replacement. Thus, thyroid disorder should be considered as an important aetiological factor for menstrual abnormality and it is one of the conditions that is easily treatable.

CONCLUSION
Thyroid dysfunction should be considered as an important aetiological factor for menstrual abnormality. Biochemical estimation of T3, T4 and TSH should be made mandatory in abnormal uterine bleeding, especially if other structural pathologies and endometrial pathologies are ruled out. Evaluation of thyroid in abnormal uterine bleeding would also avoid unnecessary surgeries and exposure to hormones, as it is easily treated and thus improves quality of life.
