ABSTRACT

The urinary stone disease is one of the most common afflictions of the modern society and it has been described since antiquity with the westernization of global culture. The efficacy of mini-invasive therapies, such as Extracorporeal Shock Wave Lithotripsy [ESWL] and ureteroscopy are not risk free, are problematic and are quite expensive. Recently, the use of watchful waiting approach has been extended by using Pharmacotherapy. This can reduce symptoms and facilitate stone expulson.

MATERIALS AND METHODS

This prospective randomised study was conducted between September 2015 and May 2016 at Rajarajeshwari Medical College and Hospital, Bangalore. The cohort comprised 100 adult patients (54 men and 46 women) who presented with a symptomatic, unilateral, single, uncomplicated lower ureteric stone of ≤ 10 mm. Patients were randomized into two equal groups, 50 (50%) patients received a daily single dose of tamsulosin 0.4 mg for 28 days and 50 (50%) patients received a daily single dose of silodosin 8 mg for 28 days. Both groups were compared in terms of patient’s demographics, socioeconomic status, stone size and side, type of MET, stone expulsion rate, stone expulsion time, number of pain episodes, need for analgesics use and incidence of side effects. Subgroup analysis was performed according to stone size ≤ or > 5 mm.

RESULTS

No significant differences among the two groups for patient’s age, gender, stone side and stone size. Spontaneous stone expulsion rate within 28 days was observed in 44 (88%) patients in the tamsulosin group and in 45 (90%) patients in the silodosin group without statistically significant differences. There were no statistically significant differences observed in terms of mean expulsion time, mean number of pain episodes and need for analgesics. Retrograde ejaculation was significantly higher in the silodosin arm, while the incidence of side effects related to peripheral vasodilation were higher in the tamsulosin arm, but it was statistically insignificant.

CONCLUSION

Tamsulosin and silodosin are equally effective as MET for distal ureteric stones sized 10 mm or smaller. MET with silodosin is associated with a lower incidence of side effects related to peripheral vasodilation, but a higher incidence of retrograde ejaculation when compared to tamsulosin. However, a multicentre study on a larger scale is needed to evaluate the current medicines.

KEYWORDS

Tamsulosin, Silodosin, Stone Expulsion Rate, Medical Expulsion Therapy (MET).

INTRODUCTION

The urinary stone disease is one of the most common afflictions of the modern society and it has been described since antiquity with the westernization of global culture, affecting 13% of men and 7% of women.\(^{(1)}\) The life-time risk of urinary stone disease is estimated to be between 5% and 12% in Europe and US among all urinary tract stones, 20% present as ureteral stones of which 70% are found in the lower third of the ureter.\(^{(2)}\) The efficacy of mini-invasive therapies, such as Extracorporeal Shock Wave Lithotripsy [ESWL] and ureteroscopy has been proven by several studies.\(^{(3)}\)

Nevertheless, these techniques are not risk free, are problematic and are quite expensive.\(^{(4)}\) Recently, the use of watchful waiting approach has been extended by using Pharmacotherapy. This can reduce symptoms and facilitate stone expulsion.\(^{(5)}\)

Both the AUA\(^{(6)}\) and the European Association of Urology (EAU)\(^{(7)}\) recommend α-blockers for the treatment of ureteric stones. Recently, the α1A-adrenoceptor subtype has been shown to play the major role in mediating phenylephrine-induced contraction of the human isolated ureter.\(^{(8)}\) In the human ureter, silodosin (A selective α1-adrenoceptor blocker) was found to be more effective than an α1D-adrenoceptor blocker in noradrenaline-induced contraction.\(^{(9)}\)

However, published data are limited on the use of silodosin as MET for DUS; thus we conducted a prospective randomized study to compare the efficacy and safety of silodosin vs tamsulosin as MET for single, symptomatic, uncomplicated lower ureteric stones in adults.
MATERIALS AND METHODS
This prospective randomised study was conducted between September 2015 and May 2016 at Rajarajeshwari Medical College and Hospital, Bangalore. The cohort comprised 100 adult patients (54 men and 46 women) who presented with a symptomatic, unilateral, single, uncomplicated lower ureteric stone of ≤ 10 mm.

Inclusion Criteria
1. Male or female patients, aged 20 and over.
2. Patients having ureteral calculi located in lower ureter on computed tomography of kidney, ureter and bladder.
3. Patients whose calculi measures 10 mm and less.
4. Patients who voluntarily decide to take part in this study and give written consent.

Exclusion Criteria
1. Patients who did not give consent and were not willing to take part in the study.
2. Pregnant women or nursing mothers.
3. Patients with febrile UTI or severe hydronephrosis or ulcerative disease or hypotension.
4. Patients on α-blockers or α/β blockers or CCB or steroid.
5. Patients whose urinary tracts are anatomically deformed or stenosed.
6. Patients who underwent invasive operation on their ureter before.
7. Patients whose blood creatinine levels are 1.4 mg/dL and over.
8. Single renal patients.
9. Pain resistant to conservative treatment (Non-tolerant patients).
10. Patients with NSAID drug intolerance or adverse effects of Tamsulosin/Silodosin during study.
11. Patient withdrew from the study at any time.

All patients were diagnosed by plain abdominal radiograph of the Kidneys, Ureters and Bladder (KUB), ultrasonography and non-enhanced spiral CT (in some cases). Every patient provided informed written consent after receiving information about the nature of the study, time to study end, adverse effects and the possibility of intervention if needed.

Patients were randomized into two equal groups, 50 (50%) patients received a daily single dose of tamsulosin 0.4 mg for 28 days and 50 (50%) patients received a daily single dose of silodosin 8 mg for 28 days.

Both the groups of patients were strictly instructed to drink a minimum of 2 L of water daily and to use symptomatic treatment with injection of 75 mg diclofenac on demand. All patients were advised to filter/strain their urine stream to detect stone passage and to stop the medications when the stone was expelled and report for confirmation. Patients were followed up weekly with X-ray of the kidney, ureter and bladder region and with ultrasonography.

Data analysis was done using SPSS software. Our study protocol was approved by the Hospital Research and Ethics Committee and all patients provided an informed written consent for participation.

RESULTS
Data were recorded and compared in terms of patient’s demographics, socio-economic status, stone size and side, type of MET, stone expulsion rate, stone expulsion time, number of pain episodes, need for analgesics use, incidence of side effects. Patients who experienced stone expulsion before first medication or who were lost to follow-up were excluded from the analysis. Subgroup analysis was performed according to stone size ≤ or >5 mm.

Any minimally invasive procedures like ureteroscopy, stenting, ESWL or discontinuation of MET during treatment period due to uncontrollable pain, adverse events, urinary tract infections, acute renal failure or the patient’s decision for stone removal were considered failed therapy. Absence of stone expulsion after 28 days was considered failed therapy.

Table 1: Demographic Data of Both Treatment Groups

There were no significant differences among the two groups for patient’s age, gender, stone side and stone size. Spontaneous stone expulsion rate within 28 days was observed in 44 (88%) patients in the tamsulosin group and in 45 (90%) patients in the silodosin group without statistically significant differences (Table 2). During the study period, hospitalization and ureteroscopy were required in 4 patients belonging to the tamsulosin arm and in 2 patients belonging to the silodosin arm.

There were no statistically significant differences observed in terms of mean expulsion time, mean number of pain episodes and need for analgesics. Retrograde ejaculation was significantly higher in the silodosin arm, while the incidence of side effects related to peripheral vasodilation (Dizziness, Postural hypotension, headache, nasal congestion) were higher in the tamsulosin arm, but it was statistically insignificant (Table 2).
DISCUSSION
Ureteroscopy and SWL remain the most effective treatments for DUS; however, they are expensive and not risk free. Spontaneous stone expulsion can occur in up to 50% of cases; nevertheless, many complications such as ureteric colic, UTI and hydronephrosis may occur. Recently, the use of various adjuvant medications as MET for DUS has helped to reduce pain, complications and increase the rate of stone clearance.\(^{(10,11)}\)

The α1A- and α1D-adrenoceptors are the most abundant subtypes in the distal ureter, stimulation of these α1 adrenoceptors leads to increases in both the frequency of ureteric peristalsis and the force of ureteric contractions. However, blockade of these receptors decreases basal ureteric tone, decreases peristaltic frequency and amplitude leading to a decrease in intraluminal pressure while the rate of urine transport increases and thus increasing the chance of stone passage.\(^{(12)}\) Highly selective α1A-adrenoceptor blockers have been developed to minimise the cardiovascular adverse effects while maintaining their efficacy on the urinary tract.\(^{(13)}\)

Various trials demonstrated increased stone expulsion rates using tamsulosin, doxazosin, terazosin, alfuzosin and naftopidil.\(^{(14)}\) Itoh performed the first prospective randomized study evaluating the use of silodosin in the management of ureteric stones ≤10 mm.\(^{(15)}\) Tsuzaka compared the efficacy of the selective α1D AR antagonist naftopidil and the selective α1A AR antagonist silodosin in the management of symptomatic ≤10 mm ureteral stones.\(^{(16)}\) Vittorio Imperatore et al, compared for the first time tamsulosin and silodosin in the context of MET for distal ureteric stones.\(^{(17)}\)

In patients presenting with DUS of 610 mm without the use of MET, the reported spontaneous stone clearance rates are between 35.2% and 61% with mean expulsion times ranging between 9.87 and 24.5 days.\(^{(18-21)}\) Several factors can affect spontaneous stone clearance of DUS including: stone size, site, number and also the presence or absence of ureteric smooth muscle spasm and/or submucosal oedema. Coll et al found a direct relationship between stone size and spontaneous clearance.\(^{(22)}\)

Results from our study demonstrate stone expulsion rates and stone expulsion times in patients treated with tamsulosin that are within the published ranges. Patients treated with silodosin exhibit stone expulsion rates and mean expulsion times that are comparable to those reported in the tamsulosin group.

Most trials on MET for lower ureteric stones with tamsulosin demonstrated significant lower mean number of pain episodes with respect to placebo.\(^{(21-23)}\) Results from the present study in terms of mean number of pain episodes and need for analgesics are within the published ranges for both the drugs.

In a study by Yu HG et al, tamsulosin treatment resulted in a significant reduction in mean systolic blood pressure relative to the negligible change of silodosin.\(^{(24)}\) The incidence of orthostatic hypotension with silodosin has been reported to be <3%.\(^{(25)}\)

Results from our study shows retrograde ejaculation in 5 (19.2%) patients treated with silodosin and none in tamsulosin group. The incidence of side effects related to peripheral vasodilation in tamsulosin group is 15 (30%) and silodosin group is 8 (16%), which is in accordance with most of the published studies. The lower incidence of side effects related to peripheral vasodilation associated with silodosin use make it more suitable for older patients.\(^{(26)}\)

CONCLUSION
Tamsulosin and silodosin are equally effective as MET for distal ureteric stones sized 10 mm or smaller. MET with silodosin is associated with a lower incidence of side effects related to peripheral vasodilation, but a higher incidence of retrograde ejaculation when compared to tamsulosin.
However, a multicentre study on a larger scale is needed to evaluate the current medicines.
