ABSTRACT

BACKGROUND
Peripheral nerve blocks have been shown to be an effective way of reducing spasticity. Phenol above 3% causes protein denaturation and axonal degeneration. Alcohol also causes tissue destruction such as nerve coagulation and muscle necrosis by denaturing proteins. Both are used in the management of gastroc-soleus spasticity, mainly by blocking the nerve supply to the gastrocnemius muscle.

The objectives of the study was to determine the effectiveness of 3% phenol block of the motor branches of posterior tibial nerve to the gastrocnemius muscles in the management of gastroc-soleus spasticity in hemiplegic patients.

MATERIALS AND METHODS
All hemiplegic patients aged 35 to 65 years with spasticity of gastroc-soleus grade 3 attending Physical Medicine and Rehabilitation, Regional Institute of Medical Sciences, Imphal were included in the study. Motor branches of the posterior tibial nerve to the gastrocnemius muscles were blocked with injection 3% phenol in the intervention group and 50% alcohol in control groups respectively. The spasticity was measured by using Modified Ashworth Scale (MAS) score. Followup was done at 1, 3 and 6 months. The data was analysed by using IBM SPSS Statistics for Windows, Version 21.0, Armonk, NY. Chi-square test, Mann-Whitney U test and Friedman’s test were used to test for significance with p-value < 0.05 taken as significant.

Study Design: Non-Randomised controlled trial.
Study Setting: Department of Physical Medicine and Rehabilitation, Regional Institute of Medical Sciences, Imphal.

RESULTS
At the end of first, follow-up grade 3 spasticity was seen only in 2.8% in the intervention group and 8.6% in the control group. In the 2nd follow-up there was no case of grade 3 spasticity in the intervention group, but was seen only in 2.8% in the control group. In the 3rd follow-up, proportion of patients with spasticity grade 3 was increased to 40% in the control group. However, there were no cases in the study group.

CONCLUSION
Alcohol and phenol block of gastrocnemius muscles in hemiplegic patients for the management of gastrocnemius spasticity was found to be effective, but long-lasting effects were found more in the phenol block.

KEYWORDS
Gastroc-Soleus Spasticity, Alcohol Block, Modified Ashworth Scale, Phenol Block

BACKGROUND
Stroke is one of the leading causes of mortality and morbidity. WHO clinically defines stroke as “rapid development of clinical signs and symptoms of focal neurological deficits lasting more than 24 hours or death with no apparent cause other than vascular origin.” It can be broadly divided as ischaemic (85%) and haemorrhagic (15%).

The most significant physical impact on stroke survivors is long-term disability. Patients with hemiplegia also often develop abnormal patterns of muscle activity in the paretic limbs in the weeks after stroke with overactivity of muscles primarily affecting anti-gravity muscles in the lower limb. Spasticity is a motor disorder characterised by a velocity dependent increase in tonic stretch reflexes (muscle tone) with exaggerated tendon jerks resulting from hyperexcitability of the stretch reflex as one component of the upper motor neuron syndrome. In the lower limbs, adduction and extension of the knee with equinovarus foot is the most observed pattern. Gastroc-soleus spasticity is a significant functional problem in patients with stroke, because the condition often causes difficulty in standing and walking. Peripheral nerve blocks have been shown to be an
effective way of reducing spasticity by interrupting the stretch reflex arc.³

Phenol acts as a local anaesthetic at low concentration (<2%). At concentrations higher than 3%, it causes protein denaturation and axonal degeneration with inflammation of the nervous tissue, which leads to neural destruction. Injection also causes occlusion and fibrosis in microcirculation around the nerve.⁴

Alcohol also causes tissue destruction such as nerve coagulation and muscle necrosis by denaturing proteins, but its effects changes with concentration. At low concentrations (5% - 10%), it blocks sodium and potassium channels and acts as a local anaesthetic. When 35% alcohol was applied onto nerves in animals, demyelination mostly in small fibres was seen with no axonal damage. And with 50% - 100% concentration, it causes paralysis with producing neuronal Wallerian degeneration and fibrosis.⁵ ⁶

Many studies have been conducted regarding tibial nerve branches motor point block to gastrocnemius by using neuromuscular stimulator with conflicting results. But there are only a few studies regarding alcohol and phenol block of peripheral nerves by using only surface anatomical landmark (blind technique) in the country. So this study was conducted to compare the effectiveness of alcohol and phenol block of motor nerve branches to gastrocnemius muscles in the management of gastroc-soleus spasticity.

Stroke is one of the leading causes of mortality and morbidity. The most significant physical impact on stroke survivors is long-term disability. Patients with hemiplegia also often develop abnormal patterns of muscle activity in the paretic limbs in the weeks after stroke with overactivity of muscles, primarily affecting anti-gravity muscles in the lower limb.⁵

Spasticity is a motor disorder characterised by a velocity dependent increase in tonic stretch reflexes (muscle tone) with exaggerated tendon jerks resulting from hyperexcitability of the stretch reflex, as one component of the upper motor neuron syndrome.⁶ In the lower limbs, adduction and extension of the knee with equinovarus foot is the most observed pattern. Gastroc-soleus spasticity is a significant functional problem in patients with stroke, because the condition often causes difficulty in standing and walking.⁷ Peripheral nerve blocks have been shown to be an effective way of reducing spasticity by interrupting the stretch reflex arc.⁸

Phenol acts as a local anaesthetic at low concentration (<2%). At concentrations higher than 3%, it causes protein denaturation and axonal degeneration with inflammation of the nervous tissue, which leads to neural destruction. Injection also causes occlusion and fibrosis in microcirculation around the nerve.⁹

Alcohol also causes tissue destruction such as nerve coagulation and muscle necrosis by denaturing proteins, but its effects changes with concentration. At low concentrations (5% - 10%) it blocks sodium and potassium channels and act as local anaesthetics. When 35% alcohol was applied onto nerves in animals, demyelination mostly in small fibres was seen with no axonal damage. And with 50% - 100% concentration, it causes paralysis with producing neuronal Wallerian degeneration and fibrosis.⁵ ⁶

Many studies have been conducted regarding tibial nerve branches motor point block to gastrocnemius by using neuromuscular stimulator with conflicting results. But there are only a few studies regarding alcohol and phenol block of peripheral nerves by using only surface anatomical landmark (blind technique) in the country. So this study was conducted to compare the effectiveness of alcohol and phenol block of motor nerve branches to gastrocnemius muscles in the management of gastroc-soleus spasticity.

MATERIALS AND METHODS
The non-randomised controlled trial was conducted in the Department of Physical Medicine and Rehabilitation, Regional Institute of Medical Sciences, Imphal during September 2014 to August 2016. A pretested proforma was used to collect the detailed history of the patient including background characteristics, examination findings at baseline and subsequent follow-ups. All the hemiplegic patients aged between 35 - 65 years with gastroc-soleus spasticity attending the Department of PMR, RIMS, Imphal during the study period was included in the study. Cases with stroke within 3 - 12 months, spasticity of gastroc-soleus grade 3 were included in the study. Cases with recurrent stroke, foot deformity, spasticity grade 4 and less than grade 3, taking anti-spastic drugs, history of allergic reactions to alcohol and phenol, history of previous surgeries or injections and those who were not willing to participate were excluded from the study. Sample size was calculated by taking effect size as 0.5, standard deviation of MAS score as 0.7, significance level of 5% and power of 80%. Adding 10% for loss for follow-up, the final calculated sample size was 70 (35 in each group). The participants were assigned to the treatment groups (intervention and control groups) by using haphazard allocation by alternation. In the intervention group nerve block was done using 3% phenol and in the control group 50% alcohol was given. In both the cases neurodevelopmental exercises along with Tendo-Achilles stretching exercises were given. The severity of spasticity in the study groups was assessed by using Modified Ashworth Scale (MAS) score.¹²

The patient was made to lie in prone position with both feet hanging at the edge of the couch. Two points were marked on the medial and lateral mass of the calf muscle about four fingers breadth from the popliteal crease.³ Then after strict antiseptic and aseptic precautions, 2 mL of 2% lignocaine was given over the marked areas and after about 5 mins any reduction of spasticity and clonus were checked. Then injection 3% phenol and 50% alcohol was given in the intervention and control groups respectively. Spasticity was then assessed by Modified Ashworth Scale (MAS) after 1, 3 and 6 months.

The data so collected was analysed by using SPSS version 21 and descriptive statistics like percentages, mean and standard deviations was used. Chi-square test and Friedman’s test was used to test for significance. A P-value of < 0.05 was taken as significant. Ethical approval was obtained from the Institutional Ethics Committee, RIMS, Imphal.
RESULTS
A total of 70 hemiplegic patients with gastrosoleus spasticity grade 3 who fulfilled the inclusion criteria were included in the study. The majority of the patients were within the age group of 54-65 years. Males represent about 70% of the cases.

Table 1 showed that there was no significant difference between the intervention and control groups at baseline. Majority of cases were infarcts (62.9%) and right side was involved more than the left side (60.0%) among the intervention group as compared to the controls (54.3%).

Table 2 showed that the proportion of cases with spasticity grade 2 and 3 were significantly more among the control group as compared to the intervention group (85.7% vs 65.7%), (8.6% vs 2.8%) at the end of first followup.

Table 3 showed that at the end of second follow-up 97.2% of cases in the control group had grade 1 spasticity, while in the intervention group only 19 (54.3%) had grade 1 spasticity. 16 (45.7%) cases had grade 2 spasticity in the intervention group, while none of the cases in the control group had grade 2 spasticity. This finding was found to be statistically significant.

Table 4 showed that proportion of cases with grade 3 spasticity increased to 40% in the control group, whereas in intervention group none of the cases had grade 3 spasticity and the finding was statistically significant.

Table 5 showed that the mean MAS scores at baseline and at subsequent follow-ups within both control and study groups differed significantly. The mean MAS score reduced to significantly lower levels in both studies and control groups. However, it was observed that the mean MAS score in the control group increased from second followup.

**DISCUSSION**
In this study, 70 patients with gastrocnemius spasticity of grade 3 were recruited. They were randomised into two groups, intervention and control. For the intervention group 3% phenol and for the control group 50% alcohol were used. All the cases were treated with routine neurodevelopment exercises based on Bobath’s technique. The reduction of gastrocnemius spasticity was measured by Modified Ashworth scale and follow-up was done at 1, 3 and 6 months.

Phenol neurolysis of peripheral nerves for spasticity has been well described in the literature as a neurolytic agent for the past 30 years. In a long-term follow-up study of phenol block of the tibial nerve by Petrillo et al, 92 tibial nerve blocks with phenol were performed in 59 patients for treatment of severe spasticity of foot and it was observed that the Achilles tendon reflexes was abolished, ankle clonus eliminated and passive stretch was reduced following the procedure in all patients. In this study, phenol (3%) block was given to both medial and lateral heads of gastrocnemius and there was reduction in spasticity to grade 1 in 91.4% and grade 2 in 8.6% at 6 months follow-up in the intervention group. In the control group, only 60% of cases were in grade 1 and 40% had grade 3 spasticity in control group. This means that the effect of phenol lasts longer than that of alcohol, even though both alcohol and phenol may cause protein denaturation and axonal degeneration. At 3 months improvement was dramatic in control group, that 97.1% of the patients had grade 1 spasticity. It may be due to neurolytic action of the alcohol with addition of neurodevelopment exercises based on Bobath technique. Spasticity was reduced to grade 1 in 91.4% of cases in the intervention group at 6 months follow-up, thereby demonstrating long lasting effects of phenol.
This finding was almost similar to a study conducted by Kocabas et al, where the spasticity score for the ankle plantar flexor was reduced in all 10 patients immediately after motor branch block and it was maintained over the 6 months follow-up period in 7 patients.12 Moore TJ et al in their study evaluated the use of open phenol blocks to the motor branches of the tibial nerve in adult-acquired spasticity in nine patients (six head injury and three spinal cord injury) and found that spasticity was decreased in all patients who underwent phenol injections into the motor branches of the tibial nerve and 5 patients (55.5%) were able to ambulate subsequently, which suggests that phenol injection to the motor branches of the tibial nerve safely and effectively prevents foot and ankle contractures following head or spinal cord injuries.13

Pelisser J and his team studied the chemical neurolysis using alcohol in the treatment of spasticity in hemiplegic patients and found that neurolysis with alcohol injection in the nerve trunk or at the motor point destroys the gamma fibres and reduces spasticity without impairing motor command.14

CONCLUSION

From this study, we conclude that alcohol and phenol block of gastrocnemius muscles for the management of gastrocnemius spasticity in hemiplegic patients were found to be effective. The effect of phenol lasts longer than that of alcohol. The treatment with alcohol and phenol are cheap as compared to other methods like injection of botulinum toxin. However, suitable preparation and proper storage of phenol are required.
