ABSTRACT

BACKGROUND
When it comes to corneal transplant failure, major concern is rejection. Rejection is the main reason for graft failure and neovascularisation is a predictable risk factor for rejection.

MATERIALS AND METHODS
This study was conducted at Mahatma Gandhi Memorial Govt. Hospital and KAPV. Govt. Medical College, Trichy. About 40 (Forty) patients with corneal neovascularisation due to various corneal diseases from March-2016 to August-2016 were evaluated.

RESULTS
In our study out of 40 patients, Male cases were 28 (70%) and Female cases were 12 (30%). In the age group of 10 to 30 years there were 12 patients, in 31 to 50 years 14 patients, and in 51 to 70 years 14 patients. We noted significant regression in 20 (50%), partial regression in 12 (30%) and no regression in 8 (20%). Subconjunctival bevacizumab was a safer drug and well tolerated by all the patients.

CONCLUSION
Subconjunctival bevacizumab can be used safely and effectively for corneal neovascularisation from different types of corneal disorders.

KEYWORDS
Corneal, Bevacizumab, New Vessel, Subconjunctival, Regression.

BACKGROUND
The cornea has the unique feature of being normally avascular except for small loops which invade the periphery for about 1 mm. But under pathologic conditions vessels invade the cornea from the limbal vascular plexus resulting in a wide variety of insults including:

- Infection,
- Inflammation,
- Ischaemia,
- Degeneration,
- Trauma and
  - Loss of the limbal stem cell barrier which can cause corneal neovascularisation although corneal NV can occasionally serve a beneficial role in the clearing of infections, wound healing, and in arresting stromal melts, its disadvantages are numerous.

Corneal NV often leads to tissue scarring, oedema, lipid deposition, and persistent inflammation that may significantly alter visual acuity. Corneal NV accompanies the most common causes of corneal infectious blindness in both developed (Herpetic keratitis) and developing (Trachoma and onchocerciasis) worlds, which cause millions to lose their sight.

Neovascularisation (NV) is divided into two main processes: Vasculogenesis and Angiogenesis. The former vasculogenesis is the formation of new blood vessels from bone marrow derived angioblast, while the latter is formation of new blood vessels from already present vascular structures.

Corneal NV may not only reduce visual acuity but also it results in the loss of the immune privilege of the cornea, thereby worsening the prognosis of subsequent penetrating keratoplasty (PK). Pre-existing corneal stromal blood vessels have been identified as a strong risk factor for immune rejection after corneal transplantation. Although various compounds have been shown to inhibit corneal neovascularisation in experimental and clinical situations including steroids, indomethacin, cyclosporine, methotrexate, low molecular weight heparin sulphate, rapamycin and thalidomide, there is still no clear consensus about the best treatment of corneal neovascularisation. Although steroids are the mainstay of treatment in corneal neovascularisation, they are not always effective and without complications.

VEGF in Human Corneal Tissue
Philipp et al have shown that VEGF is expressed in all three layers of inflamed cornea, including the epithelium, stroma, and endothelium. It is highly expressed in the vascular endothelial cells of limbal vessels and in newly formed vessels in the stroma and weakly in keratocytes. Therefore,
subconjunctival injection route will be better for the access of medication to limbal endothelial cells.

Rationale for Angiogenesis Inhibitors in Corneal Neovascularisation

Animal studies have supported the role of VEGF in the pathogenesis of corneal neovascularisation. In experimental models, increased levels of VEGF mRNA and protein and VEGF receptors have been demonstrated in corneal neovascularisation. Human corneal buttons with new vessels have been shown to have higher levels of VEGF and its receptors. VEGF inhibition therefore supresses corneal neovascularisation and helps improve vision or increase the chance of transplant survival.

An update on Bevacizumab

Bevacizumab (Avastin, Genentech) is a full length humanised murine monoclonal antibody, directed against all the biologically active forms of VEGF—A. Bevacizumab, the first anti-VEGF drug to be approved by the FDA was developed as an intravenous therapy for cancer patients, because VEGF is one of the major angiogenic stimuli, responsible for neovascularisation in tumors. In clinical trials, the most common adverse event caused by bevacizumab was hypertension. Bevacizumab has now been widely adopted and is arguably part of the standard of care for the treatment of neovascular AMD for many patients.

Pharmacokinetics of subconjunctivally Administered Bevacizumab

In general, drug is injected into subconjunctival space by two methods: direct trans-scleral delivery into intraocular tissues or clearance via conjunctival blood and lymphatic flow. Since IgG has a relatively high scleral permeability and has the same molecular weight as bevacizumab, some of the bevacizumab injected into the subconjunctival space may penetrate intraocular tissues including the retina/choroid, iris/ciliary body, and vitreous via the sclera. The bevacizumab level in the retina/choroid and iris/ciliary body was maintained above IC50 for 8.6 and 8.4 weeks, respectively, whereas it was maintained above 500 ng/mL for 0.3 weeks in the iris/ciliary body. The sclera consists of collagen and elastin chains that create a fibre matrix in which the pore diameter and intracellular space may determine the permeability of drugs. Negatively charged drugs have been found to have higher permeability than those with positive charges in bovine and porcine sclera. Proteoglycans in the sclera are negatively charged, which may contribute to the binding of positively charged molecules. An isoelectric point of bevacizumab has been found to be approximately 8.4. Therefore, longer T½ in the iris/ciliary body and retina/choroid after subconjunctival injection compared with those after intravitreal injection may sustain bevacizumab delivery into intraocular tissues due to scleral depot binding of bevacizumab to the scleral matrix.

Since the conjunctival blood vessels do not form a tight junction barrier, bevacizumab can enter into the blood circulation by pinocytosis and/or convective transport through paracellular pores in the vascular endothelial layer. The Fc receptor, which binds to both albumin and the Fc portion of IgG, was detected in the lymphatic vessels but not in the blood vessels of the conjunctiva. It may be that the function of the Fc receptor in the conjunctival lymphatic vessels is to act as an efflux receptor for the efficient elimination from the conjunctival space. Residual bevacizumab, other than the bevacizumab that directly permeated the sclera and was introduced into the blood circulation, may be eliminated from the conjunctival tissue into the lymphatic vessels via convective transport with lymphatic fluid.

Systemic exposure of bevacizumab when administered by intravitreal and subconjunctival injection was very similar. Bevacizumab was detected in the fellow eye treated by intravitreal or subconjunctival injection. Bevacizumab may have been transported through the systemic circulation into the fellow eye. In the fellow eye treated by intravitreal injection, bevacizumab concentration in the retina/choroid was maintained above IC50 for 8.0 weeks.

Heiduschka et al demonstrated that bevacizumab can penetrate the retina and is transported into the retinal pigment epithelium, choroid, and photoreceptors after intravitreal injection using an immunohistochemical staining assay with donkey anti-human IgG. In that study, the antibody used for the detection of bevacizumab recognised the injected bevacizumab molecule specifically. The strong intracorneal bevacizumab staining could persist for at least 3 days in the VEGF micropocket and alkali-induced corneal NV models after a single subconjunctival injection. The distribution of intracorneal bevacizumab could persist at least up to 7 days in the normal corneas. The reason for the different durations of intracorneal diffusion remains to be evaluated. Although not proven, the shorter duration of bevacizumab distribution in the vascularised corneas may be caused by the rapid absorption through the corneal vessels. In some studies, the eyes treated with bevacizumab showed significant decrease in the amount of neovascularisation especially those treated with subconjunctival bevacizumab.

Side Effects of Subconjunctivally Administered Bevacizumab

Systemic

There are several reports that have noted the systemic adverse effects of bevacizumab after intravitreal injection. These adverse effects are similar to the ones reported for intravenous administration of bevacizumab for cancer treatment, such as systemic hypertension, thromboembolic diseases and death. In addition, Shima et al found irregular vaginal bleeding as a complication in young women receiving intravitreal injection of bevacizumab. It should be noted, however, that these were small studies with a small amount of participants. Systemic adverse effects of bevacizumab may occur after subconjunctival injection, as well as after intravitreal or intravenous injection. Therefore, intravitreal or subconjunctival bevacizumab should be used with caution in elderly patients with choroidal or iris neovascularisation. However, efficacy in the fellow eye should be expected to be derived from the systemic circulation.

Ocular

Corneal epithelial defect, corneal ulcer, corneal oedema, conjunctival necrosis, anterior uveitis, and infectious endophthalmitis.
MATERIALS AND METHODS
This study was done in Mahatma Gandhi Memorial Govt. Hospital and KAPV Govt. Medical College, Tiruchirapalli during March 2016 to August 2016.

Forty eyes of forty patients with corneal neovascularisation due to various pathologies (mentioned below) have been selected for the study.

Study Design
- Interventional.
- Prospective.
- Non-randomised clinical study.

Inclusion Criteria
Vascularised Corneas of Patients with:
- Leucomatous opacity following exanthematous fever and post hydrops.
- Pseudophakic bullous keratopathy.
- Healed corneal ulcer post-trauma and infection.
- Previously failed optical keratoplasty.

Exclusion Criteria
- Patients with uncontrolled systemic hypertension with systolic blood pressure of ≥150 mmHg or diastolic blood pressure of ≥90 mmHg.
- Patients with recent myocardial infarction.
- Patients with recent cerebrovascular accidents.
- Diabetes mellitus.
- Renal, liver, and coagulation abnormalities including current anticoagulation medications.
- Current or recent systemic corticosteroid therapy or periocular corticosteroid injections to the study eye.
- Ocular or periocular malignancy.
- Pregnancy, lactating women, postmenopausal women not using adequate contraception.
- Any condition that precluded patient’s ability to comply with study requirements including completion of study.

Procedure
Patients who were referred to cornea clinic with corneal neovascularisation (mentioned above in inclusion criteria) were selected for the study.

A brief history of all the patients were taken and subjected to detailed ocular and systemic examination.

Anterior segment examination was done with slit-lamp biomicroscopy. Standardised corneal photographs were taken with 10X magnification with slit-lamp biomicroscopy using digital camera.

The off-label use of the drug and its potential risks and benefits were discussed extensively with all patients. All patients signed a comprehensive consent form before administration of the subconjunctival injection of bevacizumab.

A commercially available bevacizumab (2.5 mg/0.1 mL, 100 mg/4 mL) was prepared for each patient and placed in a tuberculin syringe using aseptic techniques-
- Topical anaesthetics (4% Xylocaine/Paracaine eye drops) and antibiotics are applied.
- The eye had been prepared with 5% povidone iodine in a standard fashion.
- Then draped with an eye mask.
- Opsite was applied.
- Using lid speculum eye was exposed.
- Bevacizumab (2.5 mg/0.1 mL) was injected subconjunctivally in the quadrant of vascularisation 1 cm from the limbus.
- Patients were instructed to apply antibiotic eye drops for 3 days 4 times a day.

Follow-Up
Follow-up visits were done on 14th day, 1st, 3rd, & 6th month post-injection. All the 40 patients completed 6 months of follow-up. At each visit, patients were checked for regression of new vessels i.e. reduction in both number and calibre of the vessel.

Main Outcome Measures
i. Regression of corneal new vessels.
ii. Efficacy and safety of subconjunctival bevacizumab.

RESULTS
In our study, the upper age limit being 70 years and lower age limit being 15 years. The mean age was 42 years.

DISCUSSION

Corneal neovascularisation remains a significant risk factor for corneal transplantation and subsequent graft failure after transplantation. The collaborative corneal transplantation study identified, in addition to several other factors, the extent of stromal vessel (Quadrants) involvement as a strong risk factor for corneal graft failure.

Various medications and surgical therapies have been attempted to reduce corneal angiogenesis including corticosteroids, non-steroidal anti-inflammatory drugs, laser photocoagulation and needle diathermy. Many of these therapies are associated with adverse effects and risks, and most of these therapies have demonstrated limited success. Furthermore, none of these treatments specifically target the inhibition of VEGF.6-7

Anti-VEGF therapy, used to reduce corneal angiogenesis, has recently granted interest based on the successful results demonstrated with intravitreal bevacizumab. Preliminary in vivo animal data have shown the potential effectiveness of bevacizumab in treating corneal neovascularisation.

This is a 6-month prospective, non-randomized clinical study to investigate the safety and efficacy of intravitreal bevacizumab for the treatment of corneal neovascularisation.

In this study, an obvious reduction in established corneal neovascularisation occurred to a different degree in each patient, and subconjunctival bevacizumab was well tolerated by all these patients. Out of 40 patients in 50% of patients, complete regression of the corneal new vessels noted at the end of 6th month. Whereas in 30% of patients only partial reduction noted i.e. reduction in calibre of vessels only, the number of new vessels was constant. In 20% of patients, both number of new vessels and the calibre was constant.

This variable response may be because of the chronicity, extent of corneal neovascularisation, amount of scarring, disease process, formulation and route of administration of the drug.7

Successful reduction of corneal neovascularisation with subconjunctival anti-VEGF therapy could play an important role in improving graft survival in patients who have pre-existing corneal neovascularisation (NV) or NV of the peripheral cornea that develops after penetrating keratoplasty. The reduction or elimination of corneal NV could therefore allow for corneal transplantation in those patients who were previously considered high risk and had contraindication to surgery.

CONCLUSION

- Subconjunctival injection of bevacizumab can be used safely and effectively for corneal neovascularisation resulting from different types of disorders.
- It may provide an additional strategy in improving success of corneal grafts in these patients.
- This is a short-term study. However, long-term follow-up is necessary to determine whether repeat injections are necessary.
