INTRODUCTION

Blunt trauma to abdomen is one of the common causes for morbidity and mortality. In blunt abdominal trauma, there may be trauma to the pancreas, tear of bowel and hollow viscous, which can result in elevated levels of serum amylase and lipase. Serum amylase and mainly serum lipase are diagnostic markers for pancreatitis according to some literature. We report a young male, who presented with complaints of acute abdominal pain, constipation and vomiting after blunt abdominal trauma with elevated serum amylase and lipase levels with normal pancreas.

Initial assessment of intra-abdominal pathology due to blunt abdominal trauma is often challenging as many injuries may not manifest during the treatment period. The manifestations may vary from being simply asymptomatic to life threatening injuries due to unavailability of accurate information about the nature of trauma. Hence, accurate diagnosis becomes very important in the management. Injury to the pancreas is not common and can result from direct penetration or through the transmission of blunt force to the retroperitoneum. Some studies report an incidence of 0.2 % cases for blunt trauma up to 1.1 % cases for penetrating trauma.¹ The role of ultrasonography (USG) and Computed Tomography (CT) in management of Blunt abdominal trauma is well established. But the role of laboratory tests in the evaluation of these patients is controversial.² In cases of Blunt trauma to abdomen, lot of causes found to cause serum amylase and serum lipase levels tend to raise. Some of these causes can be pancreatic, rupture of hollow viscus or bowel, facial and brain injury.³ It has also been found that reduced clearance of lipase can be caused by renal impairment. Thus non-pathological raise in level of pancreatic enzymes, and other miscellaneous causes such as diabetes mellitus, drugs and infections shall be included as alternative pancreatic diagnoses.³

PRESENTATION OF CASE

A 20 year old young male patient presented to the emergency department with alleged history of blunt abdominal trauma while working in a cotton factory followed by complaints of acute abdominal pain and constipation since 3 days and history of vomiting (3 episodes per day) since 2 days.

He also complained of decrease in urine output and burning micturition with no history of blood in urine and stools, chest pain, palpitations, shortness of breath, orthopnea, paroxysmal nocturnal dyspnoea. Patient had no past history of systemic hypertension, diabetes. He had no history of smoking and alcohol intake. On examination, he was ectomorphic, afebrile, pulse rate of 78 bpm, regular, his blood pressure was 130 / 80 mm hg. He had absent bilateral pitting oedema feet and on abdominal examination, there was diffuse tenderness in right quadrants of abdomen. There was guarding and rigidity of the abdomen was present.

Laboratory investigations revealed following values. haemoglobin 12.3 gm %, WBC-13,900 per cumm, platelet count 1.05 lakh per cumm, urea 69 mg / dL, creatinine 4.2 mg / dL, potassium 5.9 mmol / L, sodium 145 mmol / L, serum lactate dehydrogenase (LDH) 1290 U / L, liver function test was normal. In view of persistent acute pain in abdomen, his serum amylase and lipase were measured and was made to undergo NCCT.

His NCCT abdomen which was suggestive of hepatomegaly and right renal calculus with perinephric collection on right side and haemoperitoneum possibility of right renal injury [Figure 1] with right sided pleural effusion, pancreas was normal. Patient's ultrasonography was suggestive of raised echotexture of bilateral kidneys with lost corticomedullary differentiation, bilateral pleural effusion right more than left, grade 3 renal parenchymal disease, pancreas normal size, shape and echotexture. His serum amylase and serum lipase done on 1, 4 and 7 days [Table 1] on 1st day it came out to be 6360 U / L and 16945 U / L respectively. On day 4 serum amylase and lipase were 638 U / L and 1015 U / L and on 7th day serum amylase and lipase were 276 U / L and 781 U / L respectively. His creatine kinase (CK) was 366 U / L. ECG was normal. Patient also had decrease urine output thus he was managed with plenty of fluids and other supportive medications.

problem for diagnosis following blunt abdominal trauma as symptoms are often insidious in onset and enzyme markers (amylase and lipase) are known not to correlate with severity of injury. Recent studies suggestive of 6 hours after trauma serum amylase and lipase levels raised, and can be used as reliable indicator of injury to the pancreas, however non diagnostic within 6 hours or less after trauma.⁵ In the event that the abdominal assessment at first yields ambiguous or questionable outcomes in a haemodynamically steady patient with hyperamylasaemia, a complexity improved abdominal CT output ought to be finished. We had ruled out any obstructive pathology in abdomen by abdominal ultrasonography and by CT.⁶

Building up the nearness of pancreatic injury is an extensive test, as no single imaging methodology has been found to exceptionally compelling. In this way, for ahead of schedule and convenient conclusion of pancreatic injury, a high file of doubt must be kept up and pancreas can likewise be ordinary in an extent of wounds.⁴ In clinical renal failure Serum lipase can increase through the progression of renal dysfunction.⁷ These enzymes may also be elevated due to defect in tubular reabsorption of amylase and lipase.⁸ Reduced clearance of lipase from the circulation can occur with renal impairment or macro lipase formation. There are many potential causes other than pancreatitis for the significant elevation of lipase levels. Lipase may also be elevated as a result of other intra-abdominal pathologies arising from the stomach, bowel and hepatobiliary tract, neoplastic disease.³

In our case, laboratory tests with raised serum amylase and lipase and NCCT scan of the abdomen, suggested normal pancreas, hepatomegaly and right renal calculus with perinephric collection on right side and haemoperitoneum possibility of right renal injury with right sided pleural effusion. Thus pancreatitis was rule out and patient was treated as a case of acute kidney injury.⁹

Days	Hb (gm %)	Serum Amylase (U / L)	Serum Lipase (U / L)	Serum Creatinine (mg / dL)	Serum Urea (mg / dL)
1	12.3	6360	16945	4.2	103
4	7.7	638	1015	2.8	69
7	7.1	276	781	1.3	30

Table 1. Decreasing Trends of Serum Amylase and Serum Lipase Levels after Resolving Acute Kidney Injury

Injury to pancreas are relatively unusual but, however represent serious problem because of high morbidity and mortality rates that go with them, with morbidity rates ranging between 45 % and 60 %, and mortality rates ranging between 23.4 % and 30.2 %.⁴ Pancreatic injury is a common

CONCLUSIONS

Injury to pancreas is a common diagnostic dilemma following blunt abdominal trauma as symptoms are often insidious in onset and enzyme markers (amylase and lipase) are elevated. But serum lipase can also increase due to clinical renal failure and may tend to increase through the progression of renal dysfunction. Thus any patient with blunt trauma, raised enzymes and normal pancreas must be evaluated for acute kidney injury to prevent serious complications.
