EVALUATION OF RIGHT ILIAC FOSSA MASS-A RETROSPECTIVE STUDY

G. Raja Billy Graham¹, V. Vijayabhasker²

¹Professor, Department of General Surgery, Government Chengalpattu Medical College.
²Assistant Professor, Department of General Surgery, Melmaruvuthur Adhiparasakthi Institute of Medical Sciences and Research, Melmaruvuthur.

ABSTRACT

Mass in right iliac fossa is one of the common clinical surgical entity with varied etiologies, involving intra peritoneal organs like vermiform appendix, caecum, ileum, retroperitoneal structures like kidneys, blood vessels etc., and abdominal wall masses like desmoids tumor. To know the etiology and the various pattern of presentation of right iliac fossa mass in our institution a retrospective study was designed including all adult patients diagnosed to have a mass in right iliac fossa. Pediatric patients and female patients having a mass due to gynaecological diseases were excluded from this study. All clinical parameters, radiological investigations, biochemical investigations, endoscopy, cytology, biopsy were collected and analysed systematically.

KEYWORDS

Carcinoma Caecum, Appendicular Mass, Rif Mass, Psoas Abscess, Ileocaecal Tuberculosis, Crohn’s Disease.

INTRODUCTION

Right iliac fossa mass may arise from parietal wall or intraperitoneum or retroperitoneum. Mass may arise from right iliac regional structures or extended from adjacent structures.

Various Causes for Right Iliac Fossa Mass Parietal Wall Masses

Lipoma, desmoid tumor, pyogenic abscess and haematoma, ilea or appendicular abscess burrowing into abdominal wall.

Intraperitoneal Masses

Appendicular abscess or mass, ileo-caecal tuberculosis, carcinoma caecum, mesenteric adenitis, ileal nodes, typhilitis, Crohn’s disease, actinomycosis, distended gallblader, ovarian cysts, fibroid uterus, tubo-ovarian mass, occasionally intussusception, amoeboma, diverticular disease.

Retroperitoneal Masses

Sarcoma, aneurysm, psoas abscess, undescended testis, unascended kidney and tumour from ilium and cartilage.

Appendicular pathology is commonest cause for right iliac fossa mass. (Either appendicular mass or abscess). Other common causes are ileo-caecal tuberculosis and carcinoma caecum.

Appendicular abscess is formed by inflamed appendix adherent with dilated ileum, greater omentum and caecum.1 Appendicular abscess due to suppurative in an acute appendicitis or suppurative in an already formed appendicular mass.1 Abdominal tuberculosis is common in developing countries like India. It is sixth most common type of extrapulmonary tuberculosis. Its incidence is high in HIV infected patients.2 Ileo-caecal tuberculosis is commonest type of abdominal tuberculosis due to presence of Peyer’s patches and stasis of luminal contents favoured by ileo-caecal valve.

Commonest type of carcinoma in caecum is adenocarcinoma. Third common site in large bowel carcinoma (12%). Diet with lack of fibres and high fat increases risk. Dietary vitamins A, C, E (Antioxidants) and Zinc and high fibre diet reduces the risk. Diagnosis of right iliac fossa mass mainly depends on complete clinical examination, radiological, biochemical, microbiological and pathological investigations. Commonest cause of right iliac fossa mass in our country is appendicular mass or abscess, ileo-caecal tuberculosis and carcinoma caecum.

OBJECTIVES OF THE STUDY

To study the aetiology, pattern of presentation, management and complications in patients with right iliac fossa mass in our institution.

MATERIALS AND METHODS

This retrospective study was carried out in our institution over a period of two years from October 2010 to October 2012. All patients who are provisionally diagnosed to have mass in the right iliac fossa by clinical examination are included in the study. All data regarding age, gender, relevant history, investigations (Complete blood count, Blood grouping and Rh typing, HIV I and II, Chest radiograph, Ultrasound abdomen and pelvis, CT Scan abdomen and pelvis, IVP and barium follow through and enema, FNAC, Biopsy) were done to conclude the final diagnosis and appropriate treatment and postoperative complications and final histopathological reports were recorded in the standard forms. Cases are selected by following inclusion and exclusion criteria;

Inclusion Criteria

All the cases admitted with Right iliac fossa mass in our institution.

Exclusion Criteria

Female patients with gynaecological diseases. Paediatric age group (<12 years) patients with right iliac fossa mass.
In our study of 80 cases, 60% percent of cases are related to appendicular pathology; 20% of cases are related to ileo-caecal tuberculosis, 12.5% cases are related to carcinoma caecum, 7.5% of cases are related to various type of parietal wall and retroperitoneal causes like Psoas abscess, Retroperitoneal Schwannoma, Desmoid tumour, Rectus sheath haematoma. One case of carcinoma caecum was associated with ileo-caecal tuberculosis.

In our study of 80 cases, youngest patient was of age 13 year male, oldest patient was of age 70 year male, common age group was 20–50 years (72.5%). Appendicular pathology commonly presented in the 3rd decade followed by 4th and 2nd decade. Ileo-caecal tuberculosis is common in 20-50 years of age group, carcinoma caecum is common in 6th decade.
In our study of 80 cases, appendicular pathology either appendicular mass or abscess has incidence of 52% in males and 48% in females. In ileo-caecal tuberculosis incidence in males is 44% and in females is 56%. Carcinoma caecum is common in males (60%) than in females (40%). Overall, incidence in males is 51% and in females is 49%.

**SOCIOECONOMICAL STATUS**

In our study 60% of cases have low socio-economic status. Majority of ileo-caecal tuberculosis cases are from low socio-economic status.
Duration of illness in appendicular pathology is less than one month. In majority of ileo-caecal tuberculosis, patients had symptoms for 1–3 months. In majority of carcinoma caecum, patients had symptoms for 1-6 months.

Appendicular pathology patients are associated with pain, fever and vomiting. Majority of ileo-caecal tuberculosis patients are associated with fever and loss of weight and loss of appetite. Majority of carcinoma caecum patients had pain and mass.
Fig. 7: Pulse Rate at Admission

Majority of appendicular pathology patients had tachycardia (90-100/min) at admission.

Fig. 8: Clinical Findings

All cases included in this study had a mass.

Appendicular abscess was soft in consistency with diffuse borders and smooth surface and fixed mass. Appendicular mass was firm in consistency with regular border, smooth surface and fixed mass. Ileo-caecal tuberculosis was firm in consistency with irregular border, smooth or nodular surface and a mobility restricted mass. Carcinoma caecum had a hard mass, irregular border, smooth or nodular surface, restricted mobility and fixed in advanced stage.
In our study 35% of the patients had Haemoglobin less than 10gm/dl. Majority of ileo-caecal tuberculosis and carcinoma caecum patients had haemoglobin less than 10 mg/dl; 46% of patients had ESR less than 20mm/hour; 45% of the patients had ESR 20-50 mm/hour; 9% of the patients had ESR greater than 50mm/hour.

Among 16 patients of ileo-caecal tuberculosis, 6 of them had marked elevation of ESR and one carcinoma caecum associated with ileo-caecal tuberculosis had high ESR.

In our study 85% of the appendicular pathology patients had high CRP levels; 81% of appendicular pathology patients had leucocytosis (>11,000 cells/mm$^3$); 41% of tuberculosis associated patients had lymphocytosis.
In our study, USG abdomen and pelvis was done for all patients and most of them were diagnosed correctly. Barium study done for (9) ileo-caecal tuberculosis patients and carcinoma caecum (8) patients and all of them were diagnosed correctly. Colonoscopy done for two ileo- caecal tuberculosis and two carcinoma caecum patients. USG/CT guided FNAC done for three ileo-caecal tuberculosis patients and FNAC done for two desmoid tumour patients. CT done for 31 patients in various conditions and all of them were correctly diagnosed.

Fig. 11: Investigations

In our study 81% of patients are treated surgically; 19% of patients are treated conservatively. Conservatively treated seven appendicular mass patients did not come for interval appendicectomy. Seven ileo-caecal tuberculosis patients treated conservatively and one advanced carcinoma caecum patient was treated with palliative chemotherapy.

Fig. 12: Mode of Treatment
Among surgically treated 19 appendicular mass patients, 16 patients were treated with interval appendicectomy and 3 patients were treated with emergency appendicectomy. In 22 appendicular abscess patients, 14 patients were treated with emergency appendicectomy and 7 patients were treated with interval appendicectomy following extraperitoneal abscess drainage, one patient was treated by extraperitoneal drainage alone. Among surgically treated 9 patients of ileo-caecal tuberculosis, 4 patients were treated by emergency procedures following acute presentation and 5 patients were treated by elective procedures after initiating ATT. Among surgically treated 9 carcinoma caecum patients, 7 were treated with elective procedures and 2 patients were treated by emergency procedures for acute presentation.

Among conservatively treated 26 appendicular mass patients, 23 patients responded to Oschner-Sherren’s regimen (88%); 12% of the patients did not respond to Oschner-Sherren’s regimen were taken for emergency surgery.

**Fig. 13: Mode of Surgery**

**Fig. 14: Mode of Treatment for Appendicular Mass**
Among surgically treated 19 patients with appendicular mass, 3 cases were emergency appendicectomy, 16 cases were interval appendicectomy.

Among 22 patients with appendicular abscess, 14 patients were treated with laparotomy and drainage with emergency appendicectomy and 7 patients treated with laparotomy and drainage followed interval appendicectomy and one patient treated with laparotomy and drainage did not turned back for interval appendicectomy.

Among surgically treated 9 ileo-caecal tuberculosis patients, 3 patients are treated with laparotomy and adhesiolysis with biopsy, another 5 patients are treated with laparotomy and adhesiolysis with limited resection, one ileal perforation patient was treated with emergency laparotomy and limited resection.

Among surgically treated 9 carcinoma caecum patients, 7 patients are treated with right radical hemicolectomy electively and emergency right radical hemicolectomy was done for one patient who presented with acute right colo-colic intussusception, another one perforated patient was treated with emergency laparotomy and ileostomy. Laparotomy and excision biopsy was done for retroperitoneal Schwannoma patient. Wide excision and parietal wall reconstruction was done for parietal wall desmoid tumour patients. Psoas abscess patients were treated with extraperitoneal drainage and ATT. Rectus sheath haematoma patient was treated by evacuation.

**DURATION OF INPATIENT PERIOD (DAYS)**

In our study 41% of patients had in-patient stay of less than 10 days; 59% of patients stayed for more than 10 days, these included surgically treated ileo-caecal tuberculosis and carcinoma caecum cases. Most of the interval appendicectomy patient's hospitalisation is more than 10 days.
POSTOPERATIVE COMPLICATIONS

Commonest post-operative complication is wound infection, commonly associated with emergency appendicectomy in either appendicular mass or abscess. One case of faecal fistula is associated with appendicular abscess; another case is associated with ileo-caecal tuberculosis. One case of incisional hernia followed an emergency appendicular abscess drainage procedure.

POSTOP FOLLOWUP IN SURGICAL PATIENTS

In our study 95% of post-operative patients are on regular followup. Surgically treated 8 and conservatively treated 7 ileo-caecal tuberculosis patients, abdominal tuberculosis associated one carcinoma caecum patient and 2 psoas abscess patients are on regular follow-up with ATT (DOTS-I). One ileo-caecal tuberculosis, one carcinoma caecum patient expired in post-operative period out of surgically treated 65 patients.

DISCUSSION

Mass in the right iliac fossa is one of the common entity in surgical practice. Evaluation of right iliac fossa mass is essential for management and outcome.

In our study of “Evaluation of Right Iliac Fossa Mass” was made at our institution Chengalpattu Medical College from October 2010 to October 2012; 80 cases of right iliac fossa mass were studied. Among 80 cases, majority of the cases are from rural, low socio-economic group. In our study the commonest cause of right iliac mass is appendicular pathology (Either appendicular mass-32.5% or appendicular abscess-27.5%) followed by ileo-caecal tuberculosis-20% and carcinoma caecum-12.5% other rare causes -7.5%.

APPENDICULAR PATHOLOGY

In our study, appendicular pathology (Either appendicular mass or appendicular abscess) constituted 60%. According to Schwartz’ principles of surgery, male-to-female ratio in appendicular pathology is 1.2-1.3:1, in our study male-to-female ratio is 1.1:1, which is comparable.

In our study of appendicular pathology 100% of patients had pain and 69% had fever, 40% had vomiting and anorexia, 88% had tachycardia and common age group is 10–60 years
Okafor PI et al. said common symptoms in appendicular mass and appendicular abscess are pain, fever, dyspepsia, anorexia and tender palpable RIF mass and the commonest age group is 2nd to 6th decade, which is comparable in our study.

Majority of patients had symptoms for less than one month duration and only a few patients had abdominal mass as a symptom, and most of appendicular pathology patients are not anaemic, had mild elevation of ESR, and raised heart rate in 88% of cases. Oliak. D et al. said factors at admission, pain, fever, tachycardia like symptoms and blood investigations had 86% sensitivity and 58% specificity, which is comparable.

In our study 85% of patients had elevated C-reactive protein and 81% had leukocytosis. Gronross. J N et al. said leukocytosis is an early marker in appendicular pathology and raised CRP is a late marker and if leucocyte count and CRP are normal that condition is unrelated to appendicular mass or abscess, which is comparable. Gronross JM. S et al. said that appendicular mass or abscess can be ruled out in an adult patient if total leucocyte count and CRP are within normal limits.

In our study, 88% of appendicular mass patients responded to Oschner-Sherren’s regimen. Among 26 appendicular mass patients, 3 patients (12%) failed conservative management and were taken up for emergency appendicectomy. All conservatively treated patients are advised interval appendicectomy, 62% patients (16) underwent interval appendicectomy and 26% of patients (7) did not come back for interval appendicectomy.

Erdogan D. S et al. said Oschner-Sherren regimen for appendicular mass is safe and interval appendicectomy is advisable, which favours our study.

In our study, among 22 appendicular abscess patients, emergency extraperitoneal abscess drainage was done for all, along with drainage 14 patients (64%) underwent emergency appendicectomy and 7 patients (32%) underwent interval appendicectomy after 3 months, and 1 patient (4%) did not come back for interval appendicectomy. Zarba. J et al. said emergency appendicectomy with abscess drainage is the mode of treatment for appendicular abscess with low morbidity and minimal hospitalization and minimal health cost and post-operative morbidity only 9%. Out of 9%, wound infection is 75% and wound dehiscence is 25%, which is comparable.

Among 49 appendicular pathology patients 7 patients were treated conservatively, 1 patient treated with abscess drainage only, 23 patients treated with interval appendicectomy and 17 patients treated with emergency appendicectomy. Among 17 patients treated with emergency appendicectomy 6 patients developed wound infection, 1 patient developed faecal fistula, among those 6 patients who developed wound infection, 1 patient developed incisional hernia.

All emergency appendicectomy patients HRE report was acute appendicitis and for all interval appendicectomy patients HRE report was chronic appendicitis. Most of the post-operative complications occurred in emergency appendicectomy done for appendicular mass or appendicular abscess. Interval appendicectomy planned for either conservatively treated appendicular mass patients or post appendicular abscess drainage patients increases duration of hospital stay and cost of health, but interval appendicectomy produced very minimal post-operative complications. Hurme T. S et al. said emergency appendicectomy done for appendicular abscess in acute phase produced more complications, abscess drainage followed by interval appendicectomy healed well without complications, which is comparable. Eriksson S. P et al. said that interval appendicectomy and emergency appendicectomy for acute appendicitis had the same complication rates.

Lasson A. et al. said that percutaneous aspiration followed by interval appendicectomy for appendicular abscess is the best treatment. Recurrent appendicitis is common if abscess drainage done without interval appendicectomy. Post-operative complications are least in interval appendicectomy, which is comparable.

Conservatively treated appendicular mass patients and appendicular abscess patients treated by surgical drainage without appendicectomy are prone for recurrent appendicitis (20%) when compared to general population (15%) with no significant difference, so interval appendicectomy is controversial.

Hoffman. L et al. said only 20% of patients developed recurrence following conservative treatment of appendicular mass. Among 20%, most of the recurrence (66%) occurred within 2 years. Corefield L et al. said more than 50% of the surgeons do interval appendicectomy anticipating the recurrence rate of 10%-25% and complication rate of 23%. So a randomized control trial is needed for evaluation of this issue.

In our institution, conservatively treated 16 appendicular mass patients and surgically drained 7 appendicular abscess patients underwent interval appendicectomy (74%). Conservatively treated 26% patients did not come for follow-up and surgery.

**ILEO-CAECAL TUBERCULOSIS**

Abdominal tuberculosis is one of the important gastroenterological problem in developing countries, newer drugs and advanced socio-economic status in developed countries controlled the tuberculosis, but majority of the under developed countries had huge problem in prevention of tuberculosis, abdominal tuberculosis is a common problem in our country also. Majority of the abdominal tuberculosis patients treated conservatively in our institution.

Ileo-caecal tuberculosis constituted about 30% of abdominal tuberculosis. Commonly affected age group is 25-50 years, common symptoms are pain, fever, vomiting, weight loss and anorexia. In our institution 20% of RIF mass are due to ileo-caecal tuberculosis, 56% are females and 44% are males. Most of patients had symptoms for more than one month, 56% of patients had symptoms for 1-3 months. Commonest symptoms are pain, followed by fever and loss of weight. Majority of the patients had firm, mobile or restricted mobile, irregular mass per abdomen. 62.5% of patients are anaemic, more than 75% of patients had elevated ESR. Sharp J E. et al said 95% of the patients had elevated ESR, which is comparable in our study.

In our study, among 80 patients, 20% (16 patients) had ileo-caecal tuberculosis. Among 16 patients (19%), 3 patients had positive Mantoux test and 2 patients (13%) had Koch’s lesion on chest radiography and 8 patients (50%) had air-fluid level, one patient had pneumoperitoneum on abdomen radiography. 80% of ileo-caecal tuberculosis had elevated CRP.
CRP titres are used to assess the treatment response of the disease. 30% of the patients had lymphoysis and 44% of the patients were treated conservatively.

USG is an initial investigation for the diagnosis of ileo-caecal tuberculosis. In inconclusive cases CT, barium study, colonoscopy with biopsy, USG/CT guided FNAC like other mode of investigations were done. Laparoscopy is the useful recent modality for diagnostic and therapeutic purposes in abdominal tuberculosis. Balkhazari EJ.14 et al. said barium study with CT junction is useful for the diagnosis of the location, extent and mesenteric involvement of ileo-caecal tuberculosis lesions. Uzun Koy.15 A et al. said USG guided FNAC is a reliable investigation for ileo-caecal tuberculosis, which is comparable.

Rai S.16 et al. said that common complaints are pain and weight loss, clinical features are non-specific, and consistent laboratory findings are elevated CRP and low Hb% in more than 90% of the patients and Mantoux test was positive in 22%, which is comparable.

Immanuvel.17 C et al. said decreasing serum C-Reactive Protein titres in ileo-caecal tuberculosis is an useful indicator for treatment response; 62% of the patients had elevated serum CRP initially, after completion of ATT only 14% of the patients had raised CRP levels, which is comparable.

Barium study is a useful investigation; 44% of patients developed sub-acute intestinal obstruction and 16% patients had acute intestinal obstruction. Bowel resection and by-pass procedures are required in 16% of patients, which is comparable.

Muneef MA.20 et al. said that incidence of ileo-caecal tuberculosis is 52% in females and 48% in males and mean age is 46 years. Commonest clinical symptoms are fever, pain abdomen, weight loss in 70% of the patients, mass per abdomen in 67%, altered bowel habits in 39% of the patients and anorexia in 30% of the patients. Clinical signs are fever in 73% of the patients, ascites in 61% of the patients, mass abdomen 13% of the patients and drouthy abdomen in 9% of the patients. Mantoux test is positive in 27% of patients, CT abdomen showed ascites, peritoneal lesions and enlarged nodes in 80% of the patients.

Biopsy taken in 61% of the patients, HPE reported positive in 97% of the patients. Significant percentage of the patients recovered with medical management alone, which is comparable.

**CARCINOMA CAECUM**

Colorectal carcinoma commonly occurs after 5th decade, males are more prone than females and high prevalence rate is noted in high socio-economical group of population. In our study of RIF mass, 12.5% cases are due to carcinoma caecum and majority of the patients are in 6th decade followed by 7th and 5th decade, male to female ratio is 3:2, most of the patients are from low socio-economical group.

Stock– C.21 et al. said carcinoma caecum is more prevalent in patients more than 50 years of age, affects males more than females. Colonic carcinoma prevalence is increased in 8th decade, which is comparable.

Mohandas.22 KM et al. said male sex is predominantly affected in colonic carcinoma and increased prevalence is noted in immigrants and urban population than rural Indians due to environmental and dietary habits, which is comparable.

Majority of patients had symptoms for more than 1 month, commonest symptoms are pain, loss of weight and mass per abdomen. All cases had hard mobile or fixed RIF mass; 80% of carcinoma caecum patients were anaemic and had mild elevation of ESR. Among 10 cases of carcinoma caecum marked elevation of ESR is present in one case that had associated abdominal tuberculosis (10%).

Li J N.23 et al. said that carcinoma colon is a disease of the old age associated with anaemia and palpable mass per abdomen, right sided colonic malignancies decreased and left sided colonic malignancies are increased in current studies.

Sadahiro.24 S et al. said 26% of women and 21% of men with right sided colonic carcinoma have haemoglobin less than 10 grams percentage, which is comparable.

Forslund.25 A et al. said that low haemoglobin and elevated ESR, CEA, ALP is present in colonic carcinoma. Outcome of the patients with marked elevation of ESR and severe anaemia was poor, which is comparable.

In our study, 20% of patients had significant elevation of serum CRP titres.

Gur T.26 et al. said colonic malignancy patients had significant elevation of CRP and Chung Y C.27 et al. said outcome of the patients with elevated serum CRP was poor and one-third of the patients with advanced disease had markedly elevated CRP titres, which is comparable.
USG abdomen and pelvis was done for all patients (100%), barium study was done for 8 patients, CT scan abdomen and pelvis was done for all patients. CT scan revealed RIF mass in 8 patients, right sided colo-colic intussusception in one patient and pneumoperitoneum in another patient. Colonoscopy was done for 20% of the patients.

Storm E,28 et al. said that barium study has 91% sensitivity for diagnosis of colonic malignancies, which is comparable.

In our study, 90% of the patients are treated surgically in our institution. Among 10 patients, majority of the patients (7) were treated by right radical hemicolectomy (70%) electively and one patient (10%) with right colo-colic intussusception underwent emergency right radical hemicolectomy with primary anastomosis. Another one patient with ileal perforation, underwent emergency ileostomy and expired post-operatively due to LRI with septicemia. All other patients came for regular follow-up and were on anti-cancer chemotherapy. One patient (10%) with advanced carcinoma caecum was treated with palliative chemotherapy. For all post-operative patients HPE reports revealed various types of adenocarcinoma caecum. Among 10 carcinoma caecum patients, one patient (10%) had associated abdominal tuberculosis and was started on ATT prior to chemotherapy.

Herfath,29 C et al. said that treatment of carcinoma caecum and ascending colon presenting with obstruction, the treatment of choice was right hemicolectomy with ileostomy and transverse colostomy, which is comparable in our study.

PARIE TAL WALL AND RETROPERITONEAL CAUSES
In our study, both the parietal wall desmoid tumour patients are females in reproductive age group. USG, CT confirmed the parietal wall lesion, FNAC and excision biopsy followed by surgery confirmed the diagnosis.

Aissa,30 A et al. said that desmoid tumour is common in anterior abdominal wall, more prevalent in pregnancy and post-partum period and associated with hormonal influence. USG, CT, MRI and post-operative excisional biopsy reports are confirmatory investigations, which is comparable.

Etiology of both the psoas abscess patients was tuberculosis, both underwent extra-peritoneal drainage with ATT.

Villar F,31 C et al. said 50% of the psoas abscess is associated with skeletal tuberculosis, which is comparable in our study.

In our study, one rectus sheath haematoma patient presented as RIF mass, surgical evacuation of the haematoma was done as the conservative management failed.

Rajagopal,32 et al. said that abdominal pain in parietal wall haematoma is a rare entity and is treated conservatively and rarely require surgical intervention, which is comparable.

In our study, one retroperitoneal Schwannoma patient presented as RIF mass which was diagnosed by USG/CT/USG guided core needle biopsy. Surgical excision was done.

Rai BR,33 et al. said that pelvic Schwannoma presented as RIF mass and right sciatica, which is comparable.

In our study USG abdomen and pelvis is done for all cases and RIF mass was diagnosed in more than 95% of the patients. In inconclusive cases, various investigations like CT, barium study, colonoscopy, USG guided FNAC were done.

According to the Sabiston text book of surgery USG abdomen had 85% sensitivity and 90% specificity for diagnosis of appendicular pathology, which is comparable.

Millard FC,34 et al. said USG abdomen correctly diagnosed 97% of RIF masses, so the investigation of choice in RIF mass is USG abdomen, which is comparable.

Jain R,35 et al. said that sonographic features of abdominal tuberculosis thickened mesentery and lymphadenopathy, dilated small bowel loops and ascites were diagnosed in 98% of the patients, which is comparable.

Martinez,36 Ares D et al. said that USG abdomen is 79% sensitive and 92% specific for the diagnosis of colonic carcinoma, which is comparable.

In our study, overall post-operative morbidity is 17% and mortality is 3%. Common post-operative complication is wound infection. Most of the post-operative complications are treated conservatively.

CONCLUSION
• Right iliac fossa mass was common in 20 to 50 years of age group.
• Overall incidence was more common in males as compared to females (1.1:1). Appendicular pathology and Carcinoma caecum was more common in males as compared to females. Ileo-caecal tuberculosis was more common in females.
• The diseases were more in people from low socio-economic status and the commonest symptom was pain in abdomen.
• Appendicular pathology (60%) either in the form of appendicular mass (32.5%) or appendicular abscess (27.5%) were the commonest cause of mass in the right iliac fossa. Ileo-caecal tuberculosis (20%), carcinoma caecum (12.5%) was the other common causes of mass in the right iliac fossa.
• Ultrasound abdomen was the essential investigation and it had a sensitivity of greater than 95%.
• Normal levels of serum CRP titer essentially ruled out appendicular pathology. Serial titers were helpful in assessing the treatment response of ileo-caecal tuberculosis and in prognosis of carcinoma caecum.
• In patients with appendicular mass, initial conservative management followed by interval appendicectomy had better results with minimal complications.
• In patients with appendicular abscess, abscess drainage combined with appendicectomy in the same procedure, had high morbidity compared to patients who underwent interval appendicectomy following abscess drainage.
• A 44% of the patients with ileo-caecal tuberculosis were managed conservatively with anti-tubercular therapy (DOTS-I). Surgery was required in another 56% of the patients, of which 25% of the patients presented with acute complications needing immediate surgery; 31% of the patients presented with sub-acute intestinal obstruction due to adhesions and strictures following the initiation of anti-tubercular therapy, which later required surgical intervention.
• An 80% of the patients with carcinoma caecum underwent successful surgical resection; 20% of the patients presented with acute surgical problem requiring immediate surgery; 10% of the patients presented with advanced disease.
Most of the parietal wall and retroperitoneal conditions were treated surgically.

Early evaluation and intervention is needed to improve the patient’s outcome and to reduce the morbidity and mortality.

LIST OF ABBREVIATIONS

ADA - Adenosine deaminase
ALP - Alkaline phosphatase
ATT - Antitubercular treatment
Ca - Carcinoma
CEA - Carcinoembryonic antigen
CT - Computerised Tomography.
CRP - C-Reactive protein
DVT - Deep vein thrombosis
EGRF - Epidermal growth factor receptor
FNAC - Fine needle aspiration cytology
5-FU - 5-Fluorouracil
HIV - Human immunodeficiency virus
HPE - Histopathological examination
LIF - Left iliac fossa
LRI - Lower respiratory tract infection
MRI - Magnetic resonance imaging
NSAID - Non-steroidal anti-inflammatory drugs.
O-S - Ochsner-Sherren regimen
PCR - Polymerase chain reaction
PET - Positron emission tomography
PPD - Purified protein derivatives
RIF - Right iliac fossa
TC99 - Technetium 99
TC - Total leucocyte count
TNF - Tumor necrosis factor
USG - Ultrasonogram
VEGF - Vascular endothelial growth factor
WBC - White blood cell
Yrs - Years
