BACKGROUND
Propofol is a commonly used anaesthetic agent for induction and maintenance of anaesthesia. Its intravenous administration is associated with pain, which is reduced by different pharmacological methods. Our study evaluated comparative effectiveness of ondansetron and tramadol in reducing this pain.

MATERIALS AND METHODS
After approval by the Institutional Ethical Committee and an informed written consent, 120 American Society of Anaesthesiologist (ASA) Grade I and II patients of either sex, aged 18 - 60 years, undergoing various surgeries using general anaesthesia were selected. Patients with known hypersensitivity to propofol, ondansetron and tramadol, cardiac conduction defects and epilepsy were excluded. In our study, patients were randomly assigned to three groups of 40 patients each (Group 1, n= 40): Patients received upto 2 mL pre-treatment 50 mg tramadol in the saline, (Group 2, n= 40): 4 mg ondansetron in the saline (2 mL), (Group 3, n= 40): normal saline 2 mL. Drugs were given intravenously for a period of 10 seconds, while the venous drainage was occluded by placing an air-filled tourniquet (pressure inflated to 70 mmHg) on the upper arm by an assistant for one minute. Then patient was given intravenous propofol (1%) 2 mg/kg over a period of 10 seconds. The patient was asked a standard question “Is the injection comfortable?” The verbal response and behavioural signs such as facial grimacing, arms withdrawal or tears were recorded. A score of 0 to 3 corresponding to 0= No pain, 1= Mild pain, 2= Moderate pain and 3= Severe pain will be noted.

RESULTS
The overall incidence of pain was 85% in the saline group, which was decreased to 12.5% and 20% after tramadol and ondansetron pre-treatment respectively. Pain severity was significantly less in patients receiving drugs for pre-treatment than those receiving saline (p < 0.0001). No significant association was found between gender and incidence and severity of pain (p= 0.70). The incidence and severity of pain in patients above 50 years old was significantly less than patients below 50 years old (0.0001).

CONCLUSION
Tramadol and ondansetron pre-treatment provides a simple and safe method of reducing propofol injection pain. Both are equally effective, but ondansetron has an advantage in preventing postoperative nausea and vomiting.

KEYWORDS
Propofol, Ondansetron, Tourniquet.

BACKGROUND
Propofol is a popular anaesthetic intravenous agent, especially for brief cases, day surgery or when laryngeal mask airway is to be used. Propofol can also be used in total intravenous anaesthesia (TIVA) technique for the maintenance of anaesthesia and sedation. It has also been used for the prevention of emesis. Tracheal intubation without neuromuscular blocking agents and the treatment of pruritus. Propofol has a highest incidence of pain on injection when compared to other intravenous anaesthetic agents. The incidence of pain on induction with thiopentone is about 7%, while as that of propofol pain varies between 28% - 90% in adults during induction of anaesthesia. Propofol has been commonly used for induction and maintenance of anaesthesia, but pain of propofol injection can be extremely distressing to the patients. Pain on injection of propofol can be immediate or delayed. Immediate pain probably results from direct irritant effect and delayed pain probably results from an indirect effect via kinin cascade. Delayed pain has a latency of between 10 - 20 secs. Up to now, the mechanism of pain due to propofol injection has been unclear. Propofol belong to the group of phenols and can directly irritate the skin, mucous membrane and venous intima and could immediately stimulate nociceptors and free nerve endings. By its indirect action on the endothelium, it was considered that propofol activate the kallikrein-kinin system and releases bradykinin through producing venous dilation and hyperpermeability, which increases the contact between aqueous phase of propofol.
Wong and Cheong reported that pre-treatment with tramadol was as effective as lidocaine in alleviating pain on propofol injection. Ye et al demonstrated that ondansetron, a specific 5-HT antagonist, blocks Na channels in rat brain neurons. They also found that ondansetron is 15 times more potent than lidocaine in causing numbness when injected under the skin. Our study evaluated the incidence of pain during propofol injection and compared the effectiveness of ondansetron and tramadol to reduce pain during propofol injection.

**MATERIALS AND METHODS**

This randomised prospective double-blind clinical study was conducted in the Postgraduate Department of Anaesthesiology and Critical Care, Government Medical College, Srinagar. The study was conducted after approval by the Institutional Ethical Committee and an informed written consent was obtained from all the patients for participation in this study. Patients selected for surgery were among those already admitted in different units of the hospital. 120 American Society of Anaesthesiologists (ASA) Grade I and II patients of either sex, aged 18 - 60 years undergoing various surgeries using general anaesthesia were randomly selected. Pre-anaesthetic evaluation was done at least 24 hrs. prior to surgery. Patients with known hypersensitivity to propofol, ondansetron or tramadol or concomitant analgesic or sedative medication; presence of infection on the dorsum of the left hand; indications for rapid sequence intubation; sedative medication; presence of cardiac conduction defects; epilepsy and use of isoflurane 1.2%. The patients were extubated after administering muscle relaxation antagonist. Patients were followed up during the first 6 hours and were assessed for pain, swelling or allergic reaction at the injection site of propofol by anaesthesiologist.

### Statistical Analysis

The recorded data was compiled and entered in a spreadsheet (Microsoft Excel) and then exported to data editor of SPSS version 20.09 (SPSS Inc., Chicago, Illinois, USA). Continuous variables were summarised in the form of means and standard deviations and categorical variables were expressed as frequencies and percentages. Graphically, the data was presented by bars and pie diagrams. Analysis of Variance (ANOVA) with least significant difference (LSD) test was employed for comparing continuous variables. Chi-square test or Fisher’s exact test, whichever appropriate, was applied for comparing categorical variables. A ‘P’ value of less than 0.05 was considered statistically significant. Using GPower software (version 3.0.10) it was estimated that the least no. of patients required in each group with 80% power and 5% significance level is 40. Since we had to compare three groups in our study, therefore a total of 120 patients were included in our study.

### RESULTS

The study included 120 patients. Mean age of the patients in tramadol group (Group 1), ondansetron group (Group 2) and normal saline group (Group 3) was 41 ± 10.59 years, 42.62 ± 10.71 years and 39.57 ± 8.95 years respectively and the difference was not significant (p= 0.223). The difference in gender distribution was not significant (p= 0.521). 65% were females and 35% were males in tramadol group (Group 1), 57.5% were females and 42.5% were males in ondansetron group (Group 2) and 52.5% were females and 47.5% were males in saline group (Group 3). The overall incidence of pain was 85% in saline group (Group 3), which was reduced to 12.5% in tramadol group (Group 1) and 20% in ondansetron group (Group 2). Pain intensity decreased significantly in tramadol group (Group 1) and ondansetron group (Group 2) as compared to saline group (Group 3) [p= 0.0001] (Figure 1). Ondansetron and tramadol significantly reduced the severity of propofol injection pain compared to saline group (p= 0.0001). Efficacy of ondansetron in alleviating the

The adverse effects, if any, were noted. We injected sedative and opioid after propofol to get the most reliable response of patients. Anaesthetic induction was continued with fentanyl 2 μg/ kg and midazolam 0.03 mg/kg intravenously. Tracheal intubation was facilitated with 0.5 mg/ kg atracurium and anaesthesia was maintained with isoflurane 1.2%. The patients were extubated after administering muscle relaxation antagonist. Patients were followed up during the first 6 hours and were assessed for pain, swelling or allergic reaction at the injection site of propofol by anaesthesiologist.
incidence and severity of propofol injection pain was no different from tramadol \(p=0.546\) [Figure 2]. 37.1% females had pain and 42% males had pain and the difference was not significant \(p=0.70\). 49.5% patients above 50 years experienced pain, while only 39.2% patients below 50 years had pain \(p=0.0001\). Severity of pain above 50 years was significantly less than patients below 50 years.

**DISCUSSION**

Propofol is commonly used for induction and maintenance of anaesthesia, but pain of propofol injection can be extremely distressing to the patients. Propofol belongs to the group of phenols and can directly irritate the skin, mucous membrane and venous intima and could immediately stimulate nociceptors and free nerve endings. By its indirect action on the endothelium, it was considered that propofol activates the kallikrein-kinin system and releases bradykinin producing venous dilatation and hyperpermeability, which increases the contact between aqueous phase of propofol and free nerve endings and results in delayed pain within half a minute.

Various studies using different agents have been done to decrease the propofol induced pain such as pre-treatment with lignocaine, ephedrine, ondansetron, metoclopramide, nafamostat mesilate, opioids, thiopentone, ketamine, and venous intima and cou.\(^\text{11,12}\). McCulloch and Lees showed that the administration of lignocaine 10 mg immediately before propofol injection reduces the incidence of pain from 37.5% to 17.5% when using the veins in the back of hand. They did not use premedication and administered propofol over 20 seconds.\(^\text{13}\)

Lyons et al reported that the pre-treatment with 10 mg lignocaine seconds before propofol injection could significantly reduce the incidence of injection pain from 64% to 44%.\(^\text{14}\) Eriksson et al showed that lignocaine mixed with propofol decreased its pH resulting in a lower concentration of propofol in the aqueous phase and therefore less pain.\(^\text{15}\) Amina Bashir compared the effectiveness of intravenous lignocaine and tramadol in reducing the pain on propofol injection and showed a significant reduction in pain.\(^\text{16}\) Sushil P Ambesh showed that the ondansetron pre-treatment alleviates pain on propofol injection. Ye et al demonstrated that ondansetron, a specific 5-HT antagonist blocks sodium channels in rat brain neurons. They found that ondansetron is 15 times more potent as a local anaesthetic than lidocaine. It blocks peripheral 5-HT receptors, which are involved in nociceptive pathways.\(^\text{17}\) Ondansetron binds to the opioid µ receptors in humans and exhibits agonist actions. As a result of its multifaceted action as a sodium channel blocker, a 5-HT3 receptor antagonist and µ-opioid agonist ondansetron may potentially be used to alleviate pain due to propofol. Till date there is a little published data on efficacy of ondansetron to decrease pain on injection of propofol. Wong and Cheong reported that pre-treatment with tramadol was as effective as lidocaine in alleviating pain on propofol injection.\(^\text{18}\) Tramadol is a centrally acting weak µ-opioid receptor agonist and inhibits noradrenaline reuptake likewise promotes serotonin release. Pang et al showed that tramadol has local anaesthetics effects.\(^\text{19}\) Hamid Zahedi et al evaluated that tramadol and ondansetron significantly reduced the incidence and severity of propofol injection pain.\(^\text{20}\) In this study, we observed a high incidence of pain in 85% of patients in saline group during propofol injection which was decreased to 12.5% and 20% after tramadol and ondansetron pre-treatment respectively. Pain severity was significantly less in tramadol and ondansetron group as compared to saline group \(p=0.0001\). This study showed that the effect of ondansetron is as good as tramadol in decreasing the incidence and severity of propofol induced pain \(p=0.546\). No significant association was found between gender and incidence and severity of pain \(p=0.70\). The incidence and severity of pain in patients above 50 years was significantly less than patients below 50 years of age \(p=0.0001\).

**CONCLUSION**

Thus, we conclude that tramadol and ondansetron pre-treatment provides a simple and safe method of reducing propofol injection pain, but ondansetron has an advantage in preventing postoperative nausea and vomiting. No adverse effect was noted in any patient.
