ABSTRACT

BACKGROUND
Two hundred known diabetic patients who satisfied the selection criteria and consented were included in the study. Sample technique used was consecutive sampling. Data collection technique and tools were through a detailed ENT examination, fasting and postprandial blood sugar estimation and pure tone audiometry. The study was done at a tertiary care hospital and a hospital-based cross-sectional study design was employed.

The aim of the study was to know the association between the severity of sensorineural hearing loss, the duration of diabetes mellitus and the diabetic status.

MATERIALS AND METHODS
Two hundred known diabetic patients were included in the study. Sample technique used was consecutive sampling, Data collection technique and tools were through a detailed ENT examination, fasting and postprandial blood sugar estimation and pure tone audiometry. A hospital-based cross-sectional study design was employed. Statistical Analysis: Statistical analysis was performed using the Statistical Package for Social Sciences (SPSS). Data collected was analysed using descriptive statistical methods like frequencies, percentages, mean and standard deviation. Results were presented in the form of both tables and graphs. An inferential statistical tool like chi-square test was used. The test was considered significant at p < 0.05.

RESULTS
Severity of sensorineural hearing loss was high among the cases with greater duration of Diabetes mellitus. The prevalence of sensorineural hearing loss was more in patients having uncontrolled diabetic status (94.6%) compared to patients having controlled diabetic status (20.9%). In patients with diabetes of less than 5 years group, the prevalence of sensorineural hearing loss was 10.6%. In 5 to 10 years duration group, the prevalence was 38.6%. In 10 to 15 years duration group, the prevalence was 69.2%. In more than 15 years duration group, the prevalence was 78.9%. The prevalence of sensorineural hearing loss was more in patients having uncontrolled diabetes status (94.6%) compared to patients having controlled diabetic status (20.9%). Severity was also high among uncontrolled diabetic group.

CONCLUSION
It was found that greater the duration of diabetes, greater is the prevalence of sensorineural hearing loss. In less than 5 years duration group, prevalence was 10.6%. In 5 to 10 years duration group, prevalence was 38.6%. In 10 to 15 years duration group, prevalence was 69.2%. In more than 15 years duration group, it was 78.9%. Severity of sensorineural hearing loss was also high among the cases with greater duration of diabetes mellitus. The prevalence of sensorineural hearing loss was more in patients having uncontrolled diabetic status (94.6%) compared to patients having controlled diabetic status (20.9%). Severity was also high among uncontrolled diabetic group.

KEYWORDS
Pure Tone Audiometry, Sensorineural Hearing Loss, Diabetes Mellitus.

BACKGROUND
Diabetes mellitus is a chronic metabolic disorder due to relative or absolute lack of insulin, which result in elevated blood sugar levels. Morbidity in Diabetes mellitus is mainly due to long-term micro- and macro-vascular complications affecting blood vessels of eyes, kidneys, heart and nerves. The relationship between diabetes mellitus and hearing loss has been debated for many years. It has been postulated that the microvascular and neuropathic complications of diabetes do affect the hearing of individuals. Studies in animals have demonstrated thickening of the basement membrane of capillaries of stria vascularis. (1)

Diabetes mellitus has been implicated as independent causative factor of sensorineural hearing loss. Most audiometric studies of hearing in patients of diabetes show a mild-to-moderate sensorineural hearing loss mostly in high frequency, (2) although Celik et al (3) noted high threshold at all frequencies tested in diabetics.

In view of contradictory results regarding hearing impairment in diabetic patients, this study was done to assess the hearing threshold level in diagnosed patients of diabetes mellitus to study the correlation between the degree of

sensorineural hearing loss and the duration, severity of diabetes mellitus and its complications.

Panchu found that all the frequencies (250 to 8000 Hz) were affected in poorly controlled diabetics, that is glycosylated haemoglobin (HbA1c) > 8%, while examining the auditory acuity in type 2 diabetes mellitus in an Indian population.

Asma et al failed to establish any association between the type of treatment given and the effect on hearing thresholds in their study on conventional oral hypoglycaemic agents versus insulin therapy on pure tone average.\(^{(4)}\)

In a study conducted by Sheetal Krishnappa et al (2015), prevalence of hearing loss was high in type 2 diabetic patients (73%). Bilaterally symmetrical progressive SNHL with right sloping curve was seen in both diabetics as well as non-diabetics with hearing loss noted at all frequencies, but significantly in higher frequencies in diabetics.

However, a significant relationship was observed between HbA1c, blood sugar level and severity of hearing loss. The severity increased as the duration of diabetes increased.\(^{(5)}\) In a study conducted by Hamid Abdul Qaiyum et al (2015) in 50 diabetics and non-diabetics, the pure tone audiometric test revealed that 13 (26%) diabetic cases were having mild-to-moderate sensorineural hearing loss as against 4 (8%) non-diabetic controls. It is concluded that the diabetic patients have significantly high incidence of sensorineural hearing loss when compared to non-diabetic control group of comparable age.\(^{(6)}\)

In a study conducted by Ashish C Agarwal et al (2015) in 40 diabetic patients, majority of the patients had bilateral sensorineural hearing loss ranging in severity from minimal to mild degree. Median pure tone average (PTA) values were less in patients with good glycaemic status as compared to those with poor glycaemic status.

OAEs were absent in 30% of subjects. Age had a contributing effect on raising the hearing threshold, but gender and duration of diabetes did not show such an effect.\(^{(7)}\)

The current study aimed to document the prevalence of sensorineural hearing loss in diabetics mellitus and the association between the duration of diabetes mellitus and severity of sensorineural hearing loss.

**MATERIALS AND METHODS**

A hospital-based cross-sectional study was carried out from March 2014 to 2015. Institutional Ethical Committee approval was taken for the study. Total 200 consecutive diabetic patients (type 1 and type 2) of either gender visiting the outpatient department of medicine patients were included in the study. They were diagnosed to have diabetes mellitus according to the criteria given by the American Diabetes Association.\(^{(8)}\)

Inclusion criteria included diabetic patients were in the age limit between 30 – 55 years and patients willing to undergo the investigations.

Exclusion criteria included patients were outside the age limit of 30 - 55 years. Patients not willing to undergo pure tone audiometry testing, patients with a history of ear discharge, perforated tympanic membrane or any chronic ear discharge, history of intake of ototoxic drugs continuously for 6 months and prolonged history of exposure to noise (e.g. Industrial workers) were excluded from the study.

Besides detailed history, all the patients underwent an otoscopic examination, biochemical and routine urine investigations such as postprandial blood (PPBS), fasting blood sugar (FBS), serum urea and creatinine and urine for sugar, protein, ketones and microalbuminuria was obtained prior to the start of the study.

Pure tone audiometry was carried out in a sound treated room for the estimation of hearing threshold using a double channel GSI clinical audiometer. Pure tone thresholds were obtained at an octave between frequencies of 250 and 8000 Hz for air conduction and 250 and 4000 Hz for bone conduction.

Statistical package for social sciences (SPSS) was used to analyse the data. The data obtained was presented in the form of tables, figures, graphs and diagrams wherever necessary. An interferential statistical tool like chi-square test was used. The test was considered significant at p < 0.05.

**RESULTS**

The hospital-based cross-sectional study was carried out in 200 cases who were already diagnosed as having diabetes mellitus. The parameters that were studied are as follows:

1. SNHL and duration of diabetes.
2. Severity of SNHL and duration of DM.
3. SNHL and status of diabetes.
4. Severity of SNHL and status of DM.

**SNHL and Duration of Diabetes**

In our study, the subjects were divided into 4 groups on the basis of duration of diabetes. It is found that greater the duration of diabetes, greater is the prevalence of SNHL. The duration of DM is a significant factor responsible for SNHL in diabetics (chi-square test, p value < 0.001).

**Severity of SNHL and Duration of DM**

Among the cases with duration of DM < 5 years 76 (89.4%) cases were having normal hearing out of total 85 cases, 8 cases were having mild SNHL (9.4%) and 1 case was having moderate SNHL (1.2%). Among the cases with duration of DM of 5 - 10 years, 43 cases (61.4%) were having normal hearing. Out of 70 cases, 25 cases were having mild SNHL (35.7%) and 2 cases were having moderate SNHL (2.9%). Among the cases with duration of DM > 15 years 4 cases (21.1%) were having normal hearing. Out of total 26 cases 6 cases were having mild SNHL (23.1%), 6 cases were having moderate SNHL (23.1%) and 6 cases were having moderately severe SNHL (23.1%). Among the cases with duration of DM > 15 years 4 cases (21.1%) were having normal hearing out of total 19 cases, 2 cases were having mild SNHL (10.5%), 6 were having moderate SNHL (31.6%), 5 cases were having moderately severe SNHL (26.3%) and 2 cases were having severe SNHL (10.5%).

**SNHL and Status of Diabetes**

In our study among the 200 subjects, 37 had uncontrolled diabetes and 163 had controlled diabetes. Among the uncontrolled, 35 (9.46%) had SNHL. Among controlled group, 34 (20.9%) had SNHL. On statistical analysis, the status of DM is a significant factor responsible for SNHL in diabetics (chi-square test, p value < 0.001).
Severity of SNHL and Status of Diabetes

Out of total 200 cases, 163 cases were having controlled diabetic status and 37 cases were having uncontrolled diabetic status. Among the 163 cases of controlled DM, 129 cases (79.1%) were having normal hearing status, 30 cases were having mild SNHL (18.4%) and 4 cases were having moderate SNHL (2.5%). Among the 37 cases of uncontrolled DM 2 cases (5.4%) were having normal hearing, 11 cases were having mild SNHL (29.7%), 11 cases were having moderate SNHL (29.7%), 11 cases were having moderately severe SNHL (29.7%) and 2 cases (5.4%) were having severe SNHL. More severe type of SNHL is seen among uncontrolled diabetic group.

Table 4. Severity of SNHL and Status of Diabetes

DISCUSSION

The relationship between diabetes mellitus and sensory neural hearing loss is complex and under debate since many years supported by the bulk of conflicting literature. The crux about the effect of diabetes in SNHL lies centered around the cochlea and the neural pathways, which has been studied throughout the years in relation to duration of DM and glycaemic levels.

There is a strong correlation between the duration of diabetes and SNHL in our study. Those who are having more than 15 years of DM had a high prevalence of SNHL (78.9%). In the group with duration of DM < 5 yrs., prevalence is only 10.6%. The duration of DM is a significant factor responsible for SNHL in diabetics (chi-square test, p value < 0.001). In our study, it was found that the severity of hearing loss was proportional to the duration of DM.

According to Sheetal Krishnappa et al, there was 63% incidence of hearing loss in < 10 years of duration of diabetes as compared to 85% in > 10 years of duration. Further, as duration progressed the severity of hearing loss also increased in most of the cases.

Ashish C Agarwal et al noted that duration of DM did not have an effect on hearing status of diabetic patients.

In our study, there is a high prevalence of SNHL among uncontrolled diabetics (94.6%) compared to controlled diabetics (20.9). The control status of DM is a significant factor responsible for SNHL in diabetics (chi-square test, p value < 0.001).

The severity of SNHL was also high among uncontrolled DM group compared to controlled DM group.

Ashish C Agarwal et al noted that median pure tone average (PTA) values were less in patients with good glycaemic status as compared to those with poor glycaemic status.

Summary

Present study is a hospital-based cross-sectional study conducted on 200 diabetic patients attending medicine OPD. These patients were recruited to ENT Department for clinical and audiological evaluation.

It was found that greater the duration of diabetes greater is the prevalence of SNHL. In less than 5 years duration group, prevalence was 10.6%. In 5 to 10 years duration group, prevalence was 38.6%. In 10 to 15 years duration group, prevalence was 69.2%. In more than 15 years duration group, it was 78.9%. Severity of SNHL was also high among the cases with greater duration of DM.

The prevalence of SNHL was more in patients having uncontrolled diabetic status (94.6%) compared to patients having controlled diabetic status (20.9%). Severity was also high among uncontrolled diabetic group.

CONCLUSION

Greater the duration of DM, greater will be the prevalence of SNHL. Greater the duration of DM, higher will be the severity of SNHL. Uncontrolled diabetic status has an increased prevalence of SNHL. Severity of SNHL is high among uncontrolled diabetic group compared to controlled diabetic group.
