ABSTRACT

BACKGROUND

Impaired myocardial contractility as well as electrophysiological abnormalities in cirrhosis is called “Cirrhotic cardiomyopathy.” This chronic cardiac dysfunction characterised with electrophysiological abnormalities, such as prolongation of the QT interval occurring in the absence of any other cardiac disease.

AIM OF THE STUDY

To assess changes in QTc interval in ECG in patients of cirrhosis of liver.

MATERIALS AND METHODS

In this observational study, 50 ambulatory hemodynamically stable patients admitted in Department of General Medicine, King George Hospital, Visakhapatnam, who were diagnosed to have cirrhosis of the liver were included in the study. A detailed history and thorough physical examination was performed with special reference to cardiovascular system. Age and gender matched control group was selected for comparison with the patients. All participants in the study were subjected to electrocardiography.

RESULTS

Males 38(76%), Females 12(24%). QTc prolongation - 21 vs 1 in cirrhotic patients compared to controls, p<0.0001. Between alcoholic cirrhotics and non-alcoholic cirrhotics - QTc prolongation - 38.89% vs 43.75% (p=0.74).

CONCLUSIONS

Prolonged QTc was significantly more frequent in cirrhotic patients compared to that of the controls.

KEYWORDS

QTc Interval, Cirrhosis of Liver, Cardiomyopathy.

INTRODUCTION

Cirrhosis of liver results in disorganisation of the lobular and vascular architecture. Portal hypertension develops due to resistance to blood flow through the liver, thereby increase in portosystemic collaterals which pass the liver.

One of the manifestations of portal hypertension is hyperdynamic circulatory state due to activation of neurohumoral pathways that stimulate renal sodium retention, expansion of plasma volume. This hyperdynamic circulatory syndrome is associated with a variety of cardiovascular alterations.[1] In addition, the heart in patients with cirrhosis presents with structural and functional abnormalities that have been termed cirrhotic cardiomyopathy.[2,3]

“Cirrhotic cardiomyopathy” is a chronic cardiac dysfunction, characterised by blunted contractile responsiveness to stress and altered diastolic relaxation with electrophysiological abnormalities, such as prolongation of the QT interval, all occurring in the absence of any other cardiac disease.[4,5]

Electrophysiological changes like prolonged repolarisation and impaired cardiac excitation - contraction coupling have been demonstrated in these patients.[6,7]

Repolarisation prolongation is manifested by a prolonged QT interval on the electrocardiogram. Prolongation of QT interval can be associated with an increased risk of certain ventricular arrhythmias, particularly the “Torsade de pointes” type of ventricular tachycardia. Rate-corrected of the QT (>440msec) is found in 30%-60% of patients with cirrhosis.[6,7]

The exact mechanism leading to these electrophysiological changes is unclear. In clinical studies, severity of liver disease and circulatory dysfunction are related to prolonged QT interval. Moreover, these changes disappear after liver transplantation in most patients.[6,7]

AIM OF THE STUDY

To assess the prevalence of prolonged QTc interval in ECG in patients with cirrhosis of liver.

MATERIALS AND METHODS

Inclusion Criteria

The present study was an observational study conducted in King George Hospital of Andhra Pradesh. Fifty ambulatory hemodynamically stable patients of cirrhosis of liver irrespective of etiology were selected for the study. Age and gender matched control group was selected for comparison with the patients.

All were normal on clinical examination and did not have risk factors for cardiovascular, lung disease, any medications or acute illness.
Exclusion Criteria
Anemia, Hypertension, Diabetes, Dyslipidemia, primary cardiac or pulmonary disease, GI bleed within the previous 3 months, those on B-blocker within the previous 3 weeks, heart disease, those with intercurrent illness and those who were critically ill were excluded from the study.

RESULTS
Age and Gender
Among total of 50 patients, 38 were male and 12 were female patients. Out of 50 controls, 32 were male and rest females (Table 1). The mean age of the patients and controls was 44 years and 47 years respectively.

QTc Interval
Out of 50 patients of liver cirrhosis, 21 had prolonged QTc (>440ms) and 29 had normal QTc interval. Among controls only 1 person has prolonged QTc (>440ms) (Table 2).

The difference between cases (21/50 or 42%) compared to controls (1/50 or 2%) is statistically significant (p=0.0001).

QTc Interval between Alcoholics and Non-Alcoholics
Prolonged QTc interval was present in 7/18 (38.89%) among alcoholic cirrhotics compared to 14/32 (43.75%) among non-alcoholic cirrhotics (Table 3). The difference is not statistically significant (p=0.74).

DISCUSSION
In this study, the mean age of the patients was comparable with the control group. The main electrocardiographic change in cirrhosis is a prolongation of the QT interval adjusted for heart rate. Our study had QTc prolongation of 42% vs 2% in patients vs controls. This is comparable to the findings of Bernardi et al., where QTc was prolonged above 440ms in 46.8% of patients and 5.4% of control subjects (P=0.001).

The difference in the prevalence of prolongation of QTc among alcoholics and non-alcoholics is not statistically significant, similar to the findings noted by Bernardi et al.[9] This is unrelated to the aetiology of the liver disease and effect of alcohol.[1][9]

A prolonged QTc interval is fundamentally due to a delayed repolarization phase, which is responsible for an increased risk of ventricular arrhythmias and sudden death.[16] More likely, a latent heart failure and cardiac dysfunction are present in some patients with cirrhosis, especially in those patients with a more deranged circulation. Although overt cardiac failure is uncommon in cirrhosis, unexpected cardiac deaths have occurred following surgery in patients with cirrhosis.[11-13] suggesting that better assessment of cardiac function is needed in these patients.

This study has excluded those with very advanced hepatic dysfunction and as only a few patients of hepatic cirrhosis present in the early stage, the results essentially represent the middle of the spectrum of the disease severity. This study included only a limited spectrum of the disease is one of the drawbacks of this study design.

CONCLUSIONS
Cardiac evaluation should be a pre-requisite in patients with cirrhosis undergoing stress like surgery, because the presence of cardiac involvement adds to the morbidity and mortality.

Further studies dedicated to this purpose are required to accurately delineate the extent of correlation between severity of hepatic dysfunction and cardiac changes in cirrhotics.
