ABSTRACT

BACKGROUND
To study the pre- and post-operative characteristics and evaluate the surgical outcomes in patients undergoing external dacryocystorhinostomy for nasolacrimal duct obstruction with or without any previous episodes of dacryocystitis.

MATERIALS AND METHODS
This hospital based study was carried out at the Postgraduate Department of Ophthalmology, Government Medical College, Srinagar. A series of 76 patients with nasolacrimal duct obstruction, who underwent external dacryocystorhinostomy were studied. The preoperative evaluation included the following parameters: age, gender, residence, occupation, duration of symptoms, history of previous dacryocystitis, previous DCR, side of obstruction and presence of any other diseases (Systemic or ocular). Patients were examined at 1 week, 1 month, 3 months and 6 months following surgery. Surgical success was determined by the postoperative patency on syringing and resolution of symptoms at the end of six months. Patient satisfaction and complication rates were also assessed.

RESULTS
Out of the 76 patients evaluated, 42 were females and 34 were males. The mean age of patients was 58.6±14 years. The mean duration of symptoms was 2.7 years. Left sided obstruction was more common (41 patients) than right sided obstruction (33 patients). Bilateral obstruction was present in 2 patients; 30 patients had previous history of dacryocystitis, while 46 patients had no such history. The success rate was 88.4% for patients without previous history of dacryocystitis and 83.3% for patients with previous history of dacryocystitis.

CONCLUSION
The nasolacrimal duct obstruction is commoner in females than males in Kashmiri population. External dacryocystorhinostomy is an efficacious, safe and cost-effective treatment for nasolacrimal duct obstruction. The surgical outcome is similar in patients with and without any previous history of dacryocystitis. The complication rate is low and overall patient satisfaction is high.

KEYWORDS
Nasolacrimal Duct Obstruction, Dacryocystorhinostomy, Dacryocystitis.

The aim of this study was to evaluate the pre- and post-operative characteristics and surgical outcomes in patients who underwent DCR in our tertiary care centre.

MATERIALS AND METHODS
This study was conducted in the Postgraduate Department of Ophthalmology, Government Medical College, Srinagar for a period of two years (from April 2014 to April 2016).

Inclusion Criteria
1. Age 16 years and above.
2. Patients with complete nasolacrimal duct obstruction.
3. Patients with history of dacryocystitis.

Exclusion Criteria
Patients with history of previous endoscopic DCR, functional obstruction and inadequate followup were excluded from the study.

A proper history regarding age, residence, occupation, duration of symptoms, side of obstruction, previous history of acute dacryocystitis, previous external DCR and presence of any other disease (Systemic or ocular) was taken. An otolaryngologist was also involved in the evaluation to rule out any contraindication to external DCR.

ADC was defined clinically as symptoms of fulminant lacrimal sac inflammation/infection, erythema, pain and discharge for < 2 weeks’ duration prior to initial presentation. CDC was defined clinically as the presence of chronic low-grade inflammation and associated discharge that had been ongoing or intermittent for > 2 weeks’ duration. 9

Surgical Technique
The surgery was performed under local anaesthesia; 2% Lignocaine with 1:200000 adrenaline was injected at the junction of the inferior orbital margin with the beginning of the anterior lacrimal crest and subcutaneously in the medial canthal area. A curved incision was made 3 mm medial to the inner canthus with a #15 Bard Parker blade. A periosteal elevator was used to elevate the periosteum over the anterior lacrimal crest and into the lacrimal sac fossa, elevating the lacrimal sac and exposing the lacrimal bone. An osteotomy about 1 to 1.5 cm in diameter was created using Kerrison’s bone punch and nasal mucosa was exposed. The lacrimal sac and nasal mucosa were incised to create anterior and posterior flaps. A silicone tube was inserted and tied after which the anterior nasal and lacrimal sac mucosal flaps were Anastomosed using 6–0 vicryl. The external incision was closed in two layers.

Post-Operative Treatment
After the surgery, all patients were prescribed an oral antibiotic taken 3 times daily for 5 days after surgery (Augmentin® 625 mg Tablets co-amoxiclav (Amoxicillin and clavulanic acid)) and moxifloxacin 0.5%, dexamethasone 0.1% drops (Miliox DM - Sun Pharmaceuticals India) - four times daily for 15 days. Patients were seen at 1 week, 1 month, 3 months and 6 months after surgery. The silicone tubes were kept in situ for 6 – 16 weeks. The nasolacrimal system was evaluated anatomically by syringing. Patients were inquired about the symptoms and were asked to rate their satisfaction on a scale of 1 to 10 (1 = extremely dissatisfied to 10 = extremely satisfied). Surgical success was defined as the resolution of epiphora, no postoperative dacryocystitis and patency on syringing.

Statistical Analysis
SPSS (Version 20.0) and Microsoft Excel were used to carry out the statistical analysis of data. Continuous variables were summarised as mean and standard deviation and categorical variables as percentage. Data was presented by bar diagrams and pie charts. A t-test was used for comparing continuous variables and P value less than 0.05 was considered statistically significant.

RESULTS
A total of 76 patients who met the inclusion criteria underwent external DCR. These included 34 (44.7%) males and 42 (55.2%) females. The mean age was 58.6 ± 14 years.

61% belonged to rural areas, while 39% were from urban localities. Among males 76.4% were farmers, while among females majority (85.7%) were housewives. The commonest symptoms were watering (94.7%), conjunctivitis (26.3%) and chronic discharge (48.6%); 30 patients (39.4%) had previous episodes of dacryocystitis, while 46 (60.5%) had no such history. The mean duration of symptoms was 2.7 years.

Left sided obstruction was more common (53.9%) than right sided (43.4%), while 2.6% had bilateral involvement. No significant association of NLDO was seen with other systemic disorders like diabetes (28 patients), hypertension (48 patients) and thyroid disorders (12 patients); 15 patients had previous history of cataract surgery. None of the patients had any history of trauma.
Significant post-operative nasal bleeding was reported in 4 (5.2%) patients. Wound infection occurred in 2 patients (2.6%). No other significant complications were present. Patency on syringing and resolution of epiphora was documented in 83.3% patients with previous history of dacryocystitis and 88.4% patients without any such history (p value > 0.05). Patient satisfaction with the surgical outcome is summarised in Figure 3.

DISCUSSION

Epiphora is one of the commonest complaints of patients attending the eye outpatient departments. On evaluation, majority of these patients have a primary blockage of nasolacrimal duct system. The aim of our study was to evaluate the characteristics and surgical outcome in patients who underwent external DCR, which is considered a standard treatment for NLDO.

This study included 55.2% females and 44.7% males, which is similar to study conducted by M. Alnawaiseh et al\(^2\) (Gender [Female:Male] 97 (66.4%) : 49 (33.6%)) and most other studies.\(^{10,11}\) The smaller nasolacrimal canal diameter and hormonal factors may be responsible for the increased predilection in females. Majority of the patients were above 50 years of age. Similar results were seen by Yoon et al\(^{12}\) in their study. Left sided obstruction was more common than right sided, which is in harmony with the study conducted by Ivanesi et al,\(^{13}\) Prakash et al\(^{14}\) and Gilad et al.\(^8\) This may be due to the smaller nasolacrimal bony canal in females. Also, it has been found that the nasolacrimal duct and lacrimal fossa form a greater angle on right side than the left side. Most of the patients belonged to rural areas and were involved in outdoor work including farming. Majid et al\(^{15}\) studied the epidemiological characteristics in a group of patients undergoing dacryocystorhinostomy in Northern Iran and found a similar trend. The authors believe that continuous exposure to dust and smoke in these patients may have led to chronic sinusitis and particulate matter settling down in the conjunctival sac and subsequently in the nasolacrimal duct leading to obstruction. The mean duration of symptoms was 2.7 years. Studies by Erdol\(^6\) et al and Seider et al\(^7\) suggest that duration of obstruction is a predictive factor for external DCR success rates with earlier surgery offering a greater chance of success.

In this study, external DCR had a success rate of 83.3% in patients with history of dacryocystitis and 88.4% in patients without dacryocystitis. This is similar to study conducted by M. Alnawaiseh et al,\(^2\) in which patients with previous episodes of dacryocystitis had a success rate of 82.7% and those without previous episodes of dacryocystitis reported a success rate of 83.4%. Gilad et al\(^8\) observed 94.6% success rate in patients with dacryocystitis and 86.7% in patients without such history (P = 0.337). In our study, patients who were completely asymptomatic on followup and had patency on postoperative syringing at the end of 6 months were considered as successes. It has been seen that previous episodes of dacryocystitis correlates with shorter duration of nasolacrimal obstruction and epiphora. This shorter duration of epiphora may be responsible for similar success rates in both the groups.

There was no significant association of NLDO and dacryocystitis with other systemic illnesses including diabetes, hypertension and thyroid disorders. We could not find any studies in literature on such association.

Postoperative nasal bleeding and wound infection were the two main complications seen after surgery in our study. No other significant complication was reported suggesting that external DCR was a safe procedure. Majority of the patients were satisfied with the overall results.

Development of minimally invasive endoscopic techniques over the past few years has led to a decrease in the number of external dacryocystorhinostomies performed in specialised centres, especially in developed countries.\(^{16,17}\) However, external DCR is a cost effective and equally efficacious procedure with similar success rates and is preferable in cases where endoscopic procedures are contraindicated and in previous failed surgeries.\(^2\)

In conclusion external DCR still remains the treatment of choice for NLDO in our setup with very good postoperative results in patients with or without previous history of dacryocystitis.
