ABSTRACT

BACKGROUND
Multiple organ failure (MOF) is the main cause of death in ICUs, especially affecting septic patients. Infections are the primary outcome determinant of the MOFS in patients with septic shock. This is a prospective study conducted in DMC and H over a period of 15 months, where patients admitted to all kinds of Medicine Department ICU’s were studied.

The objective of this study is to provide data from our college to study the incidence of MOFS in septic shock patients, number of organs involvement and its influence on mortality.

MATERIALS AND METHODS
A total of 104 patients were enrolled in the study. Patients were enrolled as per inclusion criteria for septic shock. Out of total 104 patients, 64 patients (61.54%) had MOFS and 40 patients (38.46%) were without MOFS. Out of 64 patients with MOFS, 18 patients had single organ involvement with mortality rate of 11.11%, 12 patients had 2 - 3 organs involvement, mortality rate of 33.33% and 34 patients were having more than 3 organs involvement with highest mortality rate of 70.58%. UTI was found to be a major source of infection in 60.58% of patients.

RESULTS
The baseline demographic characteristics and various parameters of recovery of patients were evaluated and noted. Maximum number of patients, 29 (27.88%) were in the age group of 56 - 65 years followed by age group 46 - 55 years (22.12%).

CONCLUSION
So we conclude that MOF due to sepsis in an ICU is frequent with high mortality related to the number of failing organs, age and high APACHE II.

KEYWORDS
Multiple, Organ, Failure, Shock, Septic

Although, supportive assistance to critically ill patients has improved a great deal, the mortality rates have remained the same in the last 2 decades.[7,9] These rates are directly related to factors such as number of organs affected[7,10] and the different sources of involved systems.[5,8] So our aim is to conduct the study in our hospital to study the data related to the incidence of MOFS in septic shock patients, number of organs involvement and its influence on mortality. Sources of infections were also studied.

MATERIALS AND METHODS
A prospective observational study was conducted over a period of 15 months in Dayanand Medical College and Hospital, where patients were admitted to all kinds of Medicine Department ICU’s of Dayanand Medical College and Hospital were studied. The duration of the study was from 01st Jan 2013 to 30th March 2014. Total number of patients included in the study is 104.

Inclusion Criteria
1. Within 24 hrs. of diagnosis of septic shock as evidenced by.
A. A systemic inflammatory response syndrome as defined by.
Patients Matching Two or More of the following Criteria:
1. Fever (oral temperature > 38°C) or hypothermia (<36°C);
2. Tachypnoea (> 24 breaths/min);
3. Tachycardia (heart rate > 90 beats/min);
4. Leukocytosis (> 12,000/uL), leucopenia (< 4,000/uL) or >10% bands.

B. Evidence for nidus of infection (proven or suspected infectious aetiology).
C. Arterial blood pressure < 90 mmHg systolic or 40 mmHg, less than patient’s normal blood pressure after fluid resuscitation for at least for 1 hour or need for vasopressors to maintain systolic blood pressure > 90 mmHg.

Exclusion Criteria
1. Age < 18 years.
2. Patients on exogenous steroids for more than 3 weeks.
4. Immune compromised patients - Malignancy, HIV, Rheumatological diseases.
5. Organ transplant recipients.
6. Patients who refuse to participate in the study.
7. Pregnant patient.

Statistical analysis was done using software SPSS 17.0. Statistical method for study included chi-square.

RESULTS
The baseline demographic characteristics and various parameters of recovery of patients were evaluated and noted. Maximum number of patients, 29 (27.88%) were in the age group of 56 - 65 years followed by age group 46 - 55 years (22.12%).

It has been observed that out of 104 patients, 57.69% were males and 42.31% were females (Figure 1).

Out of the total 64 patients with MOFS, 20 (31.24%) recovered, 14 (21.88%) were DAMA and 30 (46.88%) patients expired. Out of the total 40 patients without MOFS, 25 (62.50%) recovered, 10 (25%) were DAMA and 5 (12.50%) patients expired. P-value for Expired patients in two groups is 0.007, which is statistically significant.

Figure 2. Distribution of Subjects according to MOFS (n= 104)

Out of 64 patients with MOFS 18 patients had single organ involvement, out of which 15 patients recovered, 1 was DAMA and 2 expired with a mortality rate of 11.11%. 12 patients had 2 - 3 organs involvement, out of which 5 patients recovered and 4 expired (33.33%). 34 patients were having more than 3 organs involvement. None of these patients recovered. 24 patients expired (70.58%) (Figure 3).

Figure 3. Outcome in Relation to Organ Involvement in Patients with MOFS (n= 64)

Mean APACHE score in recovered patients at 0, 24 and 48 hours was 27.13 ± 5.61, 22.78 ± 5.83 and 19.40 ± 5.28 respectively with a p-value of 0.007 (0 hr. vs. 24 hrs.), 0.001 (0 hr. vs. 48 hrs.) and 0.009 (24 hrs. vs. 48 hrs.) which is statistically significant.

Mean APACHE score in expired patients at 0, 24 and 48 hours was 30.37 ± 5.51, 33.69 ± 6.04 and 37.00 ± 5.35 respectively with a p-value of 0.041 (0 hr. vs. 24 hrs.), 0.005 (0 hr. vs. 48 hrs.) and 0.040 (24 hrs. vs. 48 hrs.) which is statistically significant.

DISCUSSION
Severe sepsis and septic shock are leading causes of death in non-coronary ICUs in developed countries (Martin et al 2003,[1] Sands et al 1997). Severe sepsis or septic shock accounts for as many deaths as acute myocardial infarction in hospitals (Angus et al 2001).[3] The first clinical
signs of sepsis include the unspecific symptoms of systemic inflammatory response (SIRS); fever, tachycardia, tachypnoea or elevation of the peripheral leucocyte count.

Sepsis and septic shock continues to be major cause of morbidity and mortality. It is the tenth most common cause of death in United States. Although, support for critically ill patients has significantly improved during the past 50 years, and knowledge about pathophysiology of conditions such as shock, acute renal failure and acute respiratory failure has also improved, patients have longer survival, but mortality remains high. Patients started dying due to complications of their diseases, rather than the diseases themselves.\[9,11\] For the first time, physicians faced an overwhelming inflammatory response, leading to a progressive deterioration of patients’ organ function with mortality rates up to 50%.\[4,11\]

Actually, MOF became the main cause of death in ICUs and since the first studies which described this entity during the 1970s, mortality remains almost the same, in spite of all the research in laboratories and ICUs.\[4,5,10,9\] The mortality of ICU septic patients ranges from 20% to 60%.\[5,10,11,12\] Poole, et al\[9\] observed a 6.6% mortality, while in our study it was 46.88%.

In the present study, patients having single major organ involvement showed a mortality rate of 11.11% (out of total 64 patients with MOFS). Patients with 2 - 3 major organ involvement had a mortality rate of 33.33% and those with more than 3 organs involvement had 70.58% mortality indicating poor prognosis in patients with MOFS.

This is in comparison to the study conducted by Elizabeth B et al\[13\] in 2001 in patients with MOFS in septic shock showing a mortality of 18% in single organ involvement, 52% in 2 - 3 organs involvement and 88% in more than 4 organs involvement.

The above studies correlate well with our study indicating a higher mortality rate in patients with MOFS. All patients included in the study were in the age group from 18 - 85 years. Maximum number of patients, 29 (27.88%) were in the age group of 56 - 65 years followed by age group 46 - 55 years (22.12%). The age distribution is comparable to the previous study done by Briegel J et al.\[14\]

Age thus plays a major role in mortality due to septicemia. Out of the total 104 patients, 60 patients (57.69%) were males and 44 patients (42.31%) were females. In male patients out of 60 patients 24 recovered (40%), 22 expired (36.66%) and 14 were DAMA (23.33%). In females out of total 44 patients, 21 recovered (47.72%), 13 expired (29.54%) and 10 were DAMA (27.72%). So in our study it has been observed that male patients have higher mortality as compared to female patients.

In our study in total 104 patients, there were total 129 sources of infection. Urinary tract was the major source of infection in 63 patients (60.58%) followed by respiratory tract in 43 patients (41.35%) of total infection sources.

In 11 (10.57%) patients, GIT was the source. Soft tissue was identified as the source of infection in 10 (9.62%) of patients. 1 patient (0.96%) each had CNS and CRBSI as source of infection.

This is comparable to the previous studies by various authors, which concluded that the lung is the primary source of infection both in sepsis and in septic shock followed by the abdomen, the urinary tract, soft tissues and primary blood stream infection (Annane et al. 2003).\[15\]

Deepak CL et al\[16\] in their study concluded that mean Apache II score in patients who died was 24.2 compared to the patients who recovered was 18.5 (p = 0.02). They observed Apache II score of > 21 have sensitivity of 76% and specificity of 60% in predicting mortality in patients with sepsis, which was statistically significant (p = 0.01).

In the present study, Apache II score at 0 hour was 28.65, at 24 hours - 27.16 and at 48 hours was 26.60 showing the declining trend with a p-value of 0 vs. 24 hrs. - 0.03 and 0 vs. 48 hrs. - 0.018 that is statistically significant.

Also mean Apache II score in recovered patients was 24±3 SD and in expired patients was 29±2 SD.

CONCLUSION
So we observed a correlation between mortality and number of systems with failure as well as between mortality and age. There was significant difference in Apache II values between survivors and non-survivors.
