ABSTRACT

BACKGROUND

Since ancient times, haemorrhoids are known to be a common anorectal disease.[1] Many of the treatments have been widely practiced since old times. In India, this condition is associated with rural areas and low socio-economic status, hence the exact prevalence is not known. Patients usually neglect the disease because of fear to come in front of society with disease and also hesitate to take treatment for it. This leads to progression of the disease and it become more severe.[2] Patients who had failed medical treatment usually need surgical treatment.[3] Suture haemorrhoidopexy (Chivate’s procedure) now also called as mucorectopexy is a new surgery invented by an Indian surgeon for managing 2nd, 3rd, 4th grades of haemorrhoids with lesser incidence of pain. It is based on the principles of blocking of blood supply and preventing the neovascularization by plication of vessels in the rectum above dentate line at two different levels and anchoring the rectal mucosa & sub mucosa to Parks Ligament.[4][5]

The objective of the study is to evaluate Chivate’s new procedure of trans-anal mucorectopexy for 3rd and 4th degree haemorrhoids for pain, bleeding, hospital stay, recurrence and complications.

MATERIALS AND METHODS

It is an observational study. A total of 35 patients with grade 3 and grade 4 haemorrhoids (symptomatic with bleeding per rectum) underwent suture mucorectopexy procedure. The study was conducted at department of general surgery, SMIMER, Surat, wherein patients presenting to us with complaints of haemorrhoids were screened and patients with 3rd and 4th degree haemorrhoids and willing to undergo surgery were selected for this study. We had collected data of 35 patients with 3rd and 4th degree haemorrhoids and operated with this procedure. The sample size has taken for convenience.

RESULTS

- Mean time required for procedure was 74.9 min.
- Mean duration of hospital stay was 4.42 days.
- Mean time to return to normal activity was 7.2 days.

Average VAS score for post-operative pain at 24 hours was 5.5, at 72 hours was 3.4, at 7th day was 1.3, at 1 month was 0.3. Commonly reported complaints include, urinary retention- 34.2% (n=12), pruritus ani- 8.5% (n=3), pain after operation requiring analgesic injections 8.5% (n=3), constipation 5.71% (n=2), bleeding PR 2.85% (n=1), rehospitalization due to urinary retention 2.85% (n=1).

CONCLUSION

Negligible recurrence rate on short term follow up along with lesser incidence of post-operative bleeding, minimal invasiveness with faster recovery or return to work will make Suture Haemorrhoidopexy a procedure of choice for grade II, III and IV haemorrhoids.

KEYWORDS

Suture Haemorrhoidopexy, Mucorectopexy.

Haemorrhoidectomy (MIPH-Minimally Invasive Procedure for Haemorrhoids) and DGHAL (Doppler Guided Haemorrhoidal Artery Ligation with recto anal repair), but the procedure works on the same principle. The literature published before shows that it is patient friendly, minimally invasive and superior as compared to conventional haemorrhoidectomy and cost effective as compared to stapled haemorrhoidectomy.[9-13]

Suture Haemorrhoidopexy (Chivate’s procedure) is a new invention by an Indian surgeon for managing 2nd, 3rd, 4th grades of haemorrhoids. It is based on the principles of blocking of blood supply and preventing the neovascularization by plication of vessels in the rectum above dentate line at two different levels and anchoring the rectal mucosa & sub mucosa to Parks Ligament.[5] In Relation to Superior Haemorrhoidal Artery, there are 3 anal Cushions at 3, 7 and 11’0 Clock Position. The main part of this cushion lies superior to the dentate line and which is covered by sensitive mucosa. Cross section shows presence of sub mucosal layer consisting vessels, muscle fibers and connective tissue between internal sphincter and Anal Cushions. Fibroelastic collagen tissue and the muscular structure of Treitz (muscularis canalis ani) are the support of piles mass. The venous plexus present in the form of sinusoids is known as ‘corpus cavernosum of recti’. [16]

Objective

Objective of the study is to evaluate Chivate’s new procedure of trans anal mucorectopexy for 3rd and 4th degree haemorrhoids for pain, bleeding, hospital stay, recurrence and complications.

MATERIALS AND METHODS

It is an observational study. A total no of 35 patients with grade 3 and grade 4 haemorrhoids (symptomatic with bleeding per rectum) underwent suture mucorectopexy procedure. The study was conducted at department of general surgery, SMIMER, Surat, wherein patients presenting to us with complaints of haemorrhoids were screened and patients with 3rd and 4th degree haemorrhoids and willing to undergo surgery were selected for this study. We had collected data of 35 patients with 3rd and 4th degree haemorrhoids and operated with this procedure. The sample size has taken for convenience. The bowel was prepared using polyethylene glycol powder in 2 litre of water and making patient to drink it in 3-4 hrs. Under the spinal anaesthesia, patient was positioned in lithotomy along with head low position, which helped in reducing piles mass in grade II, III and IV cases and we get better visual field. The anal canal was lubricated with lignocaine jelly. A proctoscope along with its obturator was inserted into anal canal. Proctoscope has groove for fibreoptic scope in its handle. The obturator was removed. The dentate line was visualized. Stitches were started at three o’clock position at a distance of 4 cm proximal to the dentate line by passing through the depth of the mucus-submucous and part of muscle, for the stitch a polyglactin 1.0 on atraumatic 36 mm ½ circle needle with 1.2 m length was used. Precaution was taken that stitch should pass only part of the rectal muscles. The first stitch was tied, and the next stitch was started 1–2 mm overlapping to the end of the first stitch, was double locked. To avoid purse sting effect, the double locking was continued for every stitch. The suturing was continued in the whole circumference of rectal mucosa at same level of first stitch. The second circumferential suture line was completed at 2 cm levels proximal to the dentate line. Because the suture lines were above the dentate line which has no somatic pain sensation so less pain incidences in the postoperative period. In short, only two circumferential suturing lines –one 4 cm and another 2 cm proximal to dentate line implemented in rectal mucosa.
Inclusion Criteria
Patients coming to surgical OPD with h/o per rectal bleeding and confirmed after routine investigations having grade II/III/ IV haemorrhoids with or without fissure of all age groups and both sexes were included in the study.

Exclusion Criteria
1. Patients with thrombosed pile, perianal hematoma, and ulcerated pile.
3. Proctitis.
4. Rectal sigmoid growth.

Statistical Analysis
The data were reported as mean ± SD and frequency. The data collected was entered into Microsoft excel spreadsheet and analysed using IBM SPSS Statistics, Version 22.

Data Collection
1. Detail history was taken.
2. Patients confirmed by P/R and proctoscopic examination.
3. Post-operative period during in hospital stay, following data was collected.
4. Post-operative hospital stay.
5. Any complication if occurred.
6. Note was made of any complications.

The information collected was about grade, previous medical or surgical treatment and defecation symptoms before and after surgery, recurrence of symptoms.

All patients were operated under spinal anaesthesia (Bupivacaine Heavy 0.5% 2.2-2.5 ml loading dose).

Various data was collected in term of time required for procedure, duration of hospital stay, return to normal activity, post-operative pain and other complication like perianal thrombosis, bleeding needing readmission, pain needing readmission, urinary retention, pruritus ani, mucosal prolapse, skin tags, constipation, tenesmus and recurrence.

Visual analogue scale was used for assessment of pain. (A score of 4 or more indicates severe pain).

All patients operated for mucorectopexy were called for follow up in OPD after 2 weeks, and then after 2 months.

RESULTS

A total of 35 patients with haemorrhoids grade III and IV (symptomatic with bleeding per rectum) underwent suture haemorrhoidopexy procedure.

Out of 35 patients, 23 (65.71%) were male and 12 (34.29%) were female. In our study, 28.5 % (n= 10) patients had grade IV haemorrhoids and 71.5 % (n= 25) had grade III haemorrhoids. Total no. of patients with grade 3 piles was 20 and with grade 4 piles was 15.

Mean time required for procedure was 74.9 min with standard deviation of 4.82.

Mean duration of hospital stay was 4.42 days with standard deviation of around 0.9 days.

Mean time to return to normal activity was 7.2 days with standard deviation of around 1.33 days.

Mean VAS (Visual analogue score) score for post-operative pain at 24 hours was 5.5 with standard deviation of around 0.7, at 72 hours was 3.4 with standard deviation of around 0.5, at 7th day was 1.3 with standard deviation of around 0.3, at 1 month was 0.3 with standard deviation of around 0.05.
Commonly reported complaints include, urinary retention was 34.2 % (n=12), pruritus ani 8.5% (n=3), bleeding PR in post-operative day 2.85% (n=1), pain which required analgesic drugs injections 8.5% (n=3), constipation 2 (n=2). One patient was presented on post-operative day 5 with urinary retention who required rehospitalization along with per urethral catheterization. There was no case of recurrence seen in 2 months of duration.

No patient had complaints of perianal hematoma, constipation, tenesmus, mucosal prolapse, or pain needing readmission.

In our study, out of 35 patients; 12 patients (7 males and 5 females) were having acute urinary retention in immediate post op period requiring urinary catheterization for same. This complication was arised may be due to post-operative pain, or may be due to effect of spinal anaesthesia and anal mucosal irritation, so further evaluation and studies are required to assess this complication by avoiding spinal anaesthesia and anal anesthesia and giving regional Perianal block/Pudendal block. Other recommendation is per urethral catheterization pre-operatively, and removed on first post-operative day.

In our study, 8.5% (n=3) patients were having complaints of pruritus ani in post-operative period which was managed by simple cleaning by warm water. This complication may have been due to irritation of anal region by frequent in and out movement of instrumentation or maybe due to foreign body sensation of the suture (Vicryl sutures). In our study 2 patient had complain of constipation which was treated with giving laxative drugs for short term period.

In our study, we have not considered the cost of treatment.

DISCUSSION

Overall, suture haemorrhoidopexy (also known as trans anal mucorectotomy) is gaining popularity due to its cost effectiveness and better results. The clinical success of suture haemorrhoidopexy procedure is dependent on the surgeon’s skills, adhering to the technical principles of suturing and right patient selection and it is found to be less painful with low recurrence and is patient friendly.

CONCLUSION

We have presented a short-term clinical outcome data of 35 patients. In spite of the limitations of the study, we can conclude that negligible recurrence rate on short term follow up along with lesser incidences of post-operative bleeding, minimal invasiveness with faster recovery or return to work will make Suture Haemorrhoidopexy as procedure of choice for grade II, III and IV haemorrhoids without complications.
