ABSTRACT

BACKGROUND
Smoking in India has been known since at least 2000 BC when cannabis was smoked and is first mentioned in the Atharvaveda, which dates back a few hundred years BC. Chronic Obstructive Pulmonary Disease (COPD) has been recognised as one of the most important causes of morbidity and mortality in chronic tobacco smokers all over the world. Cigarette smoking produces inflammatory changes in small airways, especially in respiratory bronchioles. This leads to dilatation and destruction of small airways, characterised as emphysema. The pulmonary damage induced by smoking acts slowly and may show no symptoms until pulmonary functions are lost. In present study, the pulmonary function test of smokers were compared with non-smokers, the people of Northern Bihar (Koshi region), Bihar.

MATERIALS AND METHODS
The study design is a descriptive comparative study of Lord Buddha Hospital (Central Hospital) and Associated Hospital, Lord Buddha Koshi Medical College, a tertiary care centre in Koshi Region (Northern Bihar) from January 2015 to November 2016. In the study 120 healthy male subjects, 60 smokers and 60 non-smokers were assessed for their pulmonary function test by using a computerised spirometer.

RESULTS
In the present study, bidi smoking was most common (58.33%) followed by both cigarette and bidi smoking (25.0%) and only cigarette smoking (16.67%) in smokers. The distribution of grade of smoking is shown in Table 3. Light smokers were commonest (75.00%), followed by moderate (21.67%) and heavy smokers (03.33%). Most of the smokers were in the age group of 40 - 49 years (50.0%). Majority of light smokers (53.33%) were in the age group of 40 - 49 years, moderate smokers (46.16%) in 50 - 60 years and heavy smokers (50.0%) in 50 - 60 years.

CONCLUSION
Tobacco smoking in any form, bidi or cigarette or both has significantly deleterious effects on the pulmonary functions. In this rural study area, bidi smoking was most common. Almost all the pulmonary function parameters were significantly reduced in smokers and obstructive pulmonary impairment was commonest.

KEYWORDS
Smoking, Smokers, Non-Smokers, Spirometry, Pulmonary Functions, Rural Area.

BACKGROUND
Smoking in India has been known since at least 2000 BC when cannabis was smoked and is first mentioned in the Atharvaveda, which dates back a few hundred years BC. Tobacco smoking is menace and contagious problem. Every effort is being made at government level to stop smoking. Even it has been declared as a crime and punishable act. Ordinance about penalty to cigarette smokers has been passed, but in spite of all cigarette smokers are still flourishing. Tobacco smoking is an intentionally invited health hazard.

The World Health Organisation reported that tobacco smoking killed 100 million people worldwide in the 20th century and warned that it could kill one billion people around the world in the 21st century.[1] In India, smoking is a prevalent in both urban and rural areas irrespective of mode of smoking i.e. cigarettes, bidis, pipes, cigar, hookah etc. In India, tobacco is consumed mainly in the form of bidis (54%) followed by smokeless tobacco (27%) and cigarettes (9%).[2]

Tobacco has remained as one of the most important predisposing factors responsible for so many respiratory and cardiovascular diseases. Chronic Obstructive Pulmonary Disease (COPD) has been recognised as one of the most important causes of morbidity and mortality in chronic tobacco smokers all over the world.[3]

Tobacco kills more than five million people worldwide. Use of tobacco in smoking and non-smoking form is quite common in India; about 15% to over 50% men use tobacco in this country. Thus, tobacco smoke related respiratory
diseases like COPD, lung cancer etc. are increasing rapidly. Furthermore, tobacco consumption has a deleterious effect on the course of bronchial asthma, pulmonary tuberculosis, lung function and other lung diseases. Moreover, there is an accelerated decline in lung function if airway obstruction already exists. Cigarette smoking produces inflammatory changes in small airways, especially in respiratory bronchioles. This leads to dilatation and destruction of small airways, characterised as emphysema. The pulmonary damage induced by smoking acts slowly and may show no symptoms until pulmonary functions are lost.

In a population based Delhi, the prevalence of bronchial asthma and allergic rhinitis was found to be higher than reported earlier from India. Smoking was one of the major risk factors for higher prevalence of bronchial asthma and allergic rhinitis.

Respiratory system evaluation and screening can easily be done by Pulmonary Function Tests. It is an important and useful adjunct for correlation and evaluation of the presenting complaint of patients like cough and dyspnoea, the imaging studies and pre- and post-treatment respiratory function status as well as to identify patients with no or insignificant signs and symptoms of respiratory impairment.

Keeping in mind, the huge physiological and clinical importance I decided to carry out this study. In present study the pulmonary function test of smokers were compare with non-smokers. So, it is expected that this knowledge will help in forming the norms of ventilator functions of Indian subject by giving due weightage to the interfering effect of smoking.

In view of increasing behaviour of smoking among the people of Northern Bihar, where a large population is migrant workers with poor hygiene and low socioeconomic status, this study was undertaken for a better understanding of the correlation between smoking and its effects on pulmonary functions.

MATERIALS AND METHODS
The study design is a descriptive comparative study. Lord Buddha Hospital (Central Hospital) and Associated Hospital, Lord Buddha Koshi Medical College, a tertiary care centre in Koshi Region (Northern Bihar), from January 2015 to November 2016. This study was conducted after approval from the Institutional Ethical Committee before the start of study. The study population included 120 male subjects comprising of 60 smokers and 60 non-smoker controls aged between 30-60 years. The study group was amongst general public including staff members, students and healthy attendant of the patients. The approval of Institutional Ethics Committee was taken before the start of study. Participants who met the inclusion criteria were recruited after giving information regarding the study in their vernacular language and written informed consent was obtained.

Classification based upon Smokers and Non-Smokers by WHO (1998)
1. **Smoker**: Someone who, at the time of the study, smokes any tobacco product either daily or occasionally.
2. **Non-Smoker**: Someone who, at the time of the study, did not smoke at all.

Inclusion Criteria
1. Subjects in the age range between 30 - 60 years.
2. Non-Smoker: According to definition non-smoker is a person who does not smoke tobacco.
3. Smoker: They are persons who are engaged in the inhalation and exhalation of fumes of burning tobacco from cigarette, bidi etc.
4. Every smoker must have been smoking at least six cigarettes a day.

Exclusion Criteria
1. Females will be not included in the study.
2. Known case of bronchial asthma.
3. COPD subjects.
4. Chronic infections such as tuberculosis or other infections of lungs.
5. Subjects with respiratory symptoms such as cough.
6. Pneumothorax.

Smoking Index
The average number of cigarettes/ bidis smoked per day and duration (in years) of tobacco smoking. Further, smokers were classified as per exposure level on the basis of smoking index criteria.

Smoking Habit Index
(Frequency x duration).
Non-smokers 0.
Light smokers 1-10.
Moderate smokers 11-20.
Heavy smokers more than 20.

Before Performing Pulmonary Function Test, following Points were Ascertained that the-<br>1. Subject has not consumed alcohol within four hours.
2. Has not smoked within one hour.
3. Has worn comfortable clothing, not restricting chest and abdominal movements.
4. Has not performed vigorous exercise within half an hour.

Procedure of Spirometry
For this study computerised spirometer, RMS Helios 701 was used. For performing the spirometry, each participant was allowed to rest for about 10 minutes before the procedure. The details of procedure was explained and demonstrated to each participant-<br>1. Smoking within 1 hour of procedure.
2. Performing vigorous exercise within 30 minutes of procedure.
3. Wearing clothing that substantially restricts full chest and abdominal expansion.
4. Eating a large meal within 2 hours of procedure.
5. To obtain an accurate recording: Sit up straight; Wear nose clip and get a good seal around the mouth.

The subject was asked to sit comfortably in a chair. The complete procedure was explained. All doubts if any are cleared. Subject was instructed to breathe in fully by deep inspiration with nostrils closed. Seal the lips around the
sterile mouthpiece of spirometer and forcefully expire the air out as fast and as far as possible. Best of three readings was recorded and interpreted.

Statistical Analysis
The data collected during the study was formulated into a master chart in Microsoft Office Excel and statistical analysis was done with the help of computer using statistical software package SPSS V.17 for windows. Using this software frequencies, range, mean, standard deviation and ‘p’ were calculated through student’s ‘t’ test and Chi-square test. SPSS software version 17 was used to calculate quantitative variables to check. Percentages were calculated directly for P= 0.05 was used as the accepted significance level.

RESULTS
The physical parameters of smokers and non-smokers are shown in [Table 1]. The age range of subjects was 30 - 60 years with mean age of 48.25 years in smokers and 48.15 years in non-smokers. Similarly, there was significant difference in the means of other physical parameters like height, weight, body mass index and body surface area in smokers and non-smokers.

In the present study bidi smoking was most common (58.33%) followed by both cigarette and bidi smoking (25.0%) and only cigarette smoking (16.67%) in smokers [Table 2] [Graph 1].

The distribution of light smokers were commonest (75.0%) followed by moderate (21.67%) and heavy smokers (03.33%) [Table 3] [Graph Table 1].

Most of the smokers were in the age group of 40 - 49 years (50.0%). Majority of light smokers (53.33%) were in the age group of 40 - 49 years, moderate smokers (46.16%) in 50 - 60 years and heavy smokers (50.0%) in 50 - 60 years [Table 4] [Graph Table 2].

The mean values of all the pulmonary function tests are significantly reduced in smokers compared to non-smokers. The impaired PFTs in smokers were found to be statistically highly significant by applying unpaired ‘t’ test of significance [Table 5] [Graph Table 3].

In our study, obstructive changes were most common in smokers (36.67%) followed by restrictive (3.33%) changes and mixed (5.0%) changes. Most of the non-smokers (95.0%) had normal PFT results [Table 6] [Graph 2].

The relation of type of smoking with pulmonary function tests is shown in [Table 7] [Graph Table 4]. In the present study, bidi smoking was the most common (58.33%) and it accounted for most of the obstructive lung changes (68.18%) in smokers after spirometry.

DISCUSSION

Smoking is well-known to cause respiratory disorders and pulmonary functions decline and when it co-exists with air pollution the effects could be more harmful. Tobacco smoking is widely prevalent all over the world and it continues to rise in developing countries. By 2030, the developing world is expected to have 7 million deaths annually from tobacco use.\(^\text{[12]}\)

World Health Organisation 1993 tobacco alert report, 900 billion bidi sticks are smoked per year in India alone. The national family health survey 2005 - 2006 reported 29.0% men and 8.9% women smokers, in state of Bihar, India. Cigarette smoking predominates in urban areas, where bidi smoking is the commonest type of smoking in the lower income groups of illiterate and less educated people.\(^\text{[13]}\)

This study included data on 120 subjects in the age group of 30-60 years with 60 non-smokers and 60 smokers. The study observed decreased pulmonary functions in smoker population compared to the non-smoker population. It is showed that there were statistically significant changes in pulmonary function \( (P \text{ value} < 0.05)\) between smoker and non-smoker population.

There was significant difference in the mean physical parameters like age, height, weight, body mass index and body surface area by calculating mean and standard deviation in smokers and non-smokers, thereby showing proper matching of smokers and non-smokers (Table 2). Most of the smokers smoked only bidi (58.33%) followed by both cigarette and bidi mixed (25.0%) and only cigarettes (16.67%). None of the individuals smoked tobacco in any form other than bidi or cigarettes.

Most cigarette smokers usually smoked non-filter cigarettes since. They are cheap and easily available in rural areas. Also, most smokers belonged to rural background and were of low socio-economic status.
In the smoking index it was observed that most smokers (42.0%) followed by moderate smokers (32.0%) and heavy smokers (26.0%).

In our study majority of the light smokers were in the age group of 40 - 49 years (53.33%), moderate smokers in 50 - 60 years (46.16%) and heavy smokers in 50 - 60 years (50.0%). Similarly, Burrows et al.[14] reported that there is quantitative significant relationship between impaired ventilatory function and duration and frequency of smoking.

In our study all pulmonary function parameters like FVC, FEV1, FEV1/FVC, PEFR, FEF 25% - 75% and MVV showed statistically highly significant association between smokers and non-smokers by applying unpaired t-test of significance (p < 0.001). Similar, observations showing lung function impairment in smokers were reported by Burrows et al.[14] Pandya et al.[15]

In our study out of total 120 study subjects 90 (75.0%) had normal lung functions, whereas 30 (25.0%) had impaired lung functions out of which 27 (90.0%) were smokers and only 3 (10.0%) were non-smokers. The association between smoking and impaired PFT was statistically highly significant. The smokers had 17.3 times more risk of having impaired pulmonary functions as compared to non-smokers. A fall in FVC indicates restrictive lung changes.

In the present study, obstructive lung dysfunction was commonest among those with impaired pulmonary functions in both smokers (22 out of 27, i.e. in 81.48%) and non-smokers group (3 out of 3 subjects, i.e. in 100%).

The obstructive lung changes were predominantly in only bidi smokers 15 (68.18%) followed by both cigarette and bidi smokers 05 (22.72%) and only cigarette smokers 02 (9.00%). Padmavathy[16] in a study concluded that pulmonary functions are more affected in bidi smokers than in cigarette smokers.

The diagnostic difficulties encountered were parallel to those experienced by different authors working on similar projects- Smoking is the major identified risk factor and approximately 15% of smokers developed Chronic obstructive pulmonary disease (COPD).[17] Current cigarette smoking had the higher rate of infection with C. pneumoniae. Smoking is a well-known important risk factor for COPD patients through alteration in mechanisms of the host defense system.[18,19]

Comparing the burden of tuberculosis and COPD- The aetiological agent in tuberculosis is the bacillus Mycobacterium tuberculosis which represents one of many in the family of mycobacteria. The mode of spread among humans is via aerosol droplet transmission, hence the lungs are often the focus of tuberculous disease although TB may present with disease in any organ system. In the 1998 survey of TB cases in England and Wales, 62% were noted to exhibit pulmonary involvement.[20] In that survey, 38% had sole extrapulmonary involvement and this figure appeared to be increasing when compared to previous surveys undertaken in the same region.[20,21,22,23]

Lung involvement due to non-typoid strains of Salmonella was first recognised in patients with underlying conditions such as malignancy, diabetes mellitus, corticosteroid therapy or alcohol abuse.[24] Salmonella has been rarely cited as a significant respiratory pathogen in this population.[25,26,27]

Studies on the prevalence of COPD in patients with HCV are also scant. In patients with chronic HCV infection, prevalence of COPD (17.6%) and bronchial asthma (14.7%) is significantly higher compared to that in patients with hepatitis B infection matched in age, gender and smoking status (COPD 5%, bronchial asthma 1.7%).[28,29,30] Bacterial Vaginosis are also including passive cigarette smoking status.[31]

CONCLUSION

Tobacco smoking in the form cigarette-bidi has significant deleterious effects on the pulmonary functions. In this study in rural area, bidi smoking was the most common. Almost all the pulmonary function parameters were significantly reduced in smokers and obstructive pulmonary impairment was commonest finding. There was significant decreased pulmonary function in the smoker population in comparison to the non-smoker population. Hence, the risk of respiratory mortality or morbidity is high with chronic tobacco smoking in Koshi region, Bihar.
