ABSTRACT

BACKGROUND
Peptic ulcer is a global health problem, both in terms of morbidity and mortality. There are many treatment strategies for tackling this disease including proton pump inhibitors, H 2 receptor antagonists, ulceroprotectives like prostaglandin analogues and sucralfate. But they have certain limitations like adverse effects, drug interactions and relapses. Some medicinal plants are found to be effective in treating and preventing peptic ulcer diseases. Scientific evaluation of these herbal extracts with active chemical ingredient can be beneficial to find out newer treatment modalities for peptic ulcer diseases with lesser adverse effects and drug interaction. In the present study, Curcuma longa, a plant belonging to the Zingiberaceae family was chosen for investigating its antiulcer properties.

MATERIALS AND METHODS
This is a Comparative Study. The rhizomes of Curcuma longa were collected locally. The extract was prepared by soxlet extraction with 50% ethanol. Albino rats of Wistar strain (120 - 200 grams) obtained from the animal house of medical college Thiruvananthapuram were used for the study. Sucralfate was purchased from Sigma Labs, Mumbai. Antiulcer effect of the extract was studied in the rat models, where mucosal damage was induced by ethyl alcohol.

RESULTS
Extract of Curcuma longa exhibited significant protection against alcohol induced gastric damage at dose levels of 1000 mg/kg body weight comparable to that of standard drug Sucralfate.

CONCLUSION
The present study with extract of Curcuma longa revealed that it has significant anti-ulcer activity.

KEYWORDS
Curcuma Longa, Ethyl Alcohol, Anti-Ulcer Effect, Sucralfate.

Acid and Gastrin

Patients with gastric ulcer associated with duodenal ulcer have increased postprandial gastrin and increased maximal acid output. This supports the hypothesis that defects in pyloric emptying mechanism with subsequent high gastrin release and high acid secretion predispose to peptic ulcer.

Pepsin and Pepsinogen

Postprandial pepsin secretion in gastric ulcer patients reported to be lower than normal. Raised serum PG2 and low PG1/PG2 ratios appear to be major risk factors for gastric ulcer occurring at distal third of the stomach.

Gastric emptying: - One accepted hypothesis in the pathogenesis of gastric ulceration is a delay in gastric emptying. It can be due to gastric hypomotility.

Duodenogastric Reflux

Another hypothesis for the pathogenesis of gastric ulceration is that because of abnormal motility in the antropyloric region, there is reflux of duodenal contents into the stomach, giving rise to chronic inflammation and eventually ulceration.

Mucous

The epithelial cells and mucus neck cells of the stomach secrete into its surface a layer of mucus, which is an insoluble viscous gel that entraps bicarbonate secreted by the mucus in a layer.

The Mucous

Bicarbonate barrier is thus believed to be an important mechanism that enables the gastric as well as duodenal epithelium to remain intact in the face of high concentration of luminal hydrogen ion at pH 1.5 to 2. Gastric mucosal cells will be less in the gastric mucosa of patients with gastric ulcer. A prevalence of non-secreting surface mucous cells has been observed by scanning electron microscope in patients with gastric ulcer.

Injurious Factors

The upper gastrointestinal mucosa is susceptible to injury from variety of factors. Important endogenous agents include acid, pepsin, refluxed bile acids, many cytokines, in particular tumour necrosis factor (TNF)- alpha, leukotrienes and reactive oxygen species (ROS) such as O2•−, H2O2 and OH•. Exogenous agents include ethanol, aspirin and other NSAIDS, corticosteroids, cigarette smoking, stress and H. pylori infection.

Involvement of reactive oxygen species (ROS) in the pathogenesis of gastric ulceration was evident from various studies. More than 95% of the O2 taken by the aerobic organisms is fully reduced to water (H2O) during the process of mitochondrial respiration, a small percentage (< 5%) of the O2 consumed is converted to semi-reduced species, i.e. the superoxide anion radical (O2•−), hydrogen peroxide (H2O2) and the hydroxyl radical (•OH). These species are collectively referred to as reactive oxygen species (ROS), which can be highly toxic and their interactions often with cellular macromolecules bring about oxidative damage. The most toxic of the ROS is the hydroxyl radical which is often formed when superoxide anion radical and H2O2 are exposed to the trace transition metals, iron or copper via metal-catalysed Haber-Weiss reaction.

\[ \text{Fe}^{3+} + \text{O}_2^- = \text{Fe}^{2+} + \text{O}_2 \]
\[ \text{Fe}^{2+} + \text{H}_2\text{O}_2 = \text{Fe}^{3+} + \cdot \text{OH} + \text{OH}^- \]

The net result is therefore,

\[ \text{O}_2^- + \text{H}_2\text{O}_2 = \text{O}_2 + \cdot \text{OH} + \text{OH}^- \]

Involvement of ROS in pathogenesis of gastric ulceration was evident from the studies on ischaemia-re-oxygenation-induced gastric mucosal injury. A growing body of experimental and clinical evidence suggests that gastric mucosal damage by ethanol, non steroidal anti-inflammatory drugs and Helicobacter pylori is mediated through reactive oxygen species. ROS also decreases the level of endogenous antioxidants such as α-tocopherol, glutathione and ascorbate and make the mucosa more prone to oxidative damage. In a study conducted by Debashis Bandyopadhyay and coworkers, it was found that melatonin a pineal hormone has potent anti-ulcer activity and this activity is mainly due to melatonin's potent antioxidant potential which can scavenge the reactive oxygen species. All these findings favour the involvement of reactive free radicals in gastric mucosal damage and the role of antioxidants in preventing gastric ulceration.

Protective Factors

A number of mechanisms work together to protect the mucosa from injury. Mucus-bicarbonate barrier, surface active phospholipids, prostaglandin, mucosal blood flow, cell renewal and migration, antioxidants and antioxidant enzymes and some growth factors contribute the mucosal defense against aggressive factors.

A-Gastric Mucosal Barrier

Gastric mucosa has the ability to resist the back diffusion of hydrogen (H+) ions and thus to contain a high concentration of hydrochloric acid within the gastric lumen.

The mucosal defense system can be envisioned as a three-level barrier, composed of pre-epithelial, epithelial and sub-epithelial elements. The mucous gel functions as a no stirred water layer impeding diffusion of ions and molecules such as pepsin. Bicarbonate secreted by surface epithelial cells of the gastroduodenal mucosa into the mucous gel forms, a pH gradient ranging from 1 to 2 at the gastric luminal surface and reaching 6 to 7 along the epithelial cell surface. Surface epithelial cells provide the next line of defense through several factors including mucus production and epithelial cell ionic transporters that maintain intracellular pH and bicarbonate production.
B-Cytoprotection

There are certain mediators, which play important role in cytoprotection. Epithelial cells in the surface produce bicarbonate, which diffuses up from the mucosa to accumulate beneath the mucous layer, creating a thin layer of alkalinity between the mucus and epithelial surface. Epithelial cells also secrete mucus, which form a gel that covers the mucosal surface and physically protects the mucosa. Mucosal blood flow is important in maintaining oxygenation and a supply of nutrients. The hydrophobic layer of phospholipids that coats the luminal membrane of surface epithelial cells is believed to help prevent the back diffusion of hydrophilic agents such as hydrochloric acid. The alkaline tide refers to the mild alkalinisation of the blood and mucosa that result from secretion of a molecule of bicarbonate (HCO₃⁻) by parietal cell into the adjacent mucosa for every H⁺ ion that is secreted into gastric lumen. The slight alkalinity may contribute to neutralisation of acid that diffuses back into the mucosa and may augment the effects of mucosal blood flow. Prostaglandins play a central role in gastric epithelial defense and repair. Prostaglandins synthesised in the mucosa of stomach stimulate secretion of both mucus and bicarbonate, inhibit parietal cell secretion and are important in maintaining mucosal blood flow and epithelial cell restitution.

MATERIALS AND METHODS

Study Design

Comparative Study.

Plant Material

Curcuma longa rhizomes were collected locally and identified pharmacognostically. Its botanical identity was confirmed and certified by the Pharmacognosy unit, Ayurvedic Research Institute (A.R.I), Poojappura, Thiruvananthapuram.

Preparation of Extract

After washing the rhizome, dried in air and cut into small pieces. Soxlet extraction with 50% alcohol was used for preparing the extract. The percentage yield was 4.5.

Animals Used

Albino rats of Wistar strain (120 - 200 grams) obtained from the animal house of medical college, Thiruvananthapuram, were used. They were fed a standard diet and maintained under standard laboratory conditions.

Drugs

Sucralfate was collected from Sun Pharmaceuticals, Mumbai.

Antulcer study by Ethyl Alcohol Induced Mucosal Damage in Rats

Albino rats weighing 150 - 200 of both sexes were used for the study. They were randomised into 5 groups, each group having 6 animals. They were starved for 18 hours having access to drinking water ad libitum. To prevent cannibalism and coprophagy, they were kept in single cages with raised bottoms of wide wire mesh. Aqueous preparation of extract of Curcuma longa and other compounds were given orally 30 minutes prior to 1% Ethyl alcohol administration in the following manner.

- **Group I (control):** Distilled water (1 mL/100 gram body weight).
- **Group II (standard):** Sucralfate in a dose of 250 mg/kg - body weight suspended in distilled water.
- **Group III (test group 1):** Ethanolic extract of Curcuma longa in a dose of 250 mg/kg - body weight suspended in distilled water.
- **Group IV (test group 2):** Ethanolic extract of Curcuma longa in a dose 500 mg/kg - body weight suspended in distilled water.
- **Group V (test group 3):** Ethanolic extract of Curcuma longa in a dose of 1000 mg/kg - body weight suspended in distilled water.

One mL of absolute alcohol was administered orally to all animals, 30 minutes after administering the test compounds. One hour after administering ethyl alcohol, the animals were sacrificed by giving heavy dose of ether. Stomach was removed and opened along the greater curvature. Mucosa was examined macroscopically for gastric mucosal damage located in fundic area. For each rat, the total major axis length of ethanol induced lesions was measured.

Statistical Analysis

One-Way ANOVA (Analysis of Variance) was done to compare the means in the experimental groups. Mean and standard deviation was found out. Significance of test results were done by Duncan’s Multiple Range (DMR) test (Post-Hoc analysis using DMR test).

RESULTS

Antulcer Study by Ethyl Alcohol Induced Mucosal Damage in Rats

Ethanol produced severe band-like mucosal lesions in the fundic glandular portion of the stomach. Extract of Curcuma longa exhibited significant protection against alcohol induced gastric damage at dose levels of 1000 mg/kg body weight comparable to that of standard drug Sucralfate. There was significant cytoprotective action, but in a lesser extent at 500 mg/kg doses of test drug. The extract in the dose of 250 mg/kg dose was not effective comparable to that of control. Major axis length of ulcers was 47.98 ± 1.90, 37.90 ± 3.02 and 11.27 ± 1.34 in dose levels of 250 mg/kg, 500 mg/kg and 1000 mg/kg body weight respectively. Major axis length was 9.50 ± 0.66 in the sucrafate treated group, whereas 46.32 ± 3.08 in the control group. The alcohol induced gastric lesion is a model for screening cytoprotective action of test drug. The results show significant cytoprotective action of test drug comparable to that of Sucralfate in the dose of 1000 mg/kg body weight doses. The effect was comparable with that of standard drug Sucralfate.

Table 2: Effect of Ethanolic Extract of Curcuma longa on Ethyl Alcohol Induced Gastric Lesions in Rats

J. Evolution Med. Dent. Sci./eISSN- 2278-4802, pISSN- 2278-4748/ Vol. 7/ Issue 03/ Jan. 15, 2018
Patients with gastric ulcers are reported to be due to an imbalance between offensive acid-pepsin secretion and defensive mucosal factors like mucus secretion and cell shedding. Extract of Curcuma longa found to have many protective effects on stomach. P-tolylmethylnorcarbinol, a turmeric component, was found capable of increasing bicarbonate and pancreatic enzymes secretion. It is found to increase gastric wall mucus. In another study, oral administration of Curcumin in rats caused reversal of lipid peroxidation in brain lipids and production of reduced glutathione, a non-enzymatic antioxidant. In case of peptic ulcer, inflammatory mediators play an important role along with involvement of free radical injury and lipid peroxidation. Study conducted by Iluri and coworkers shows potent acute anti-inflammatory activity of Curcuma longa in carrageenan induced paw oedema and xylene induced ear oedema and chronic anti-inflammatory activity in cotton pellet induced granuloma model. Potent antioxidant and free radical scavenging properties of Curcuma longa extract in FRAP (Ferric reducing antioxidant power) assay shown by Ranjith Thakur and coworkers may contribute to its cytoprotective action. Potent anti-inflammatory activity of Curcuma longa was shown by Anandalakumar and coworkers. Anti-inflammatory and antioxidant activity of curcuma longa was also shown in a study done by Eshatseyoglu T et al.

Free radical scavenging antioxidant and increasing glutathione levels may contribute to the anti-ulcer effect of curcumin. Mahady GB and coworkers showed anti H. pylori effect for the extract of Curcuma longa. H. pylori is a gram-negative spiral bacterium that is associated with chronic gastritis, peptic ulcer and a risk factor for gastric malignancies such as adenocarcinoma and mucosa associated lymphoid tissue (MALAT) lymphoma. In a study conducted by Soney EK and coworkers, diarylheptanoids separated from ethanolic extract of curcuma longa found to have free radical scavenging activity in vitro. Thus, the potent anti-inflammatory activity of Curcuma longa extract and curcumin may help in the acute and chronic peptic ulcer management complicated by concomitant H. pylori infection. The anti-cancer properties may also be helpful in the long-term treatment of peptic ulcer complicated by H. pylori infection since infection with H. pylori is considered as a risk factor for gastric malignancies.

Oxygen free radicals are implicated in the pathogenesis of ethanol induced gastric mucosal injury apart from other mechanisms, such as mucosal leucotriene release and submucosal venular constriction. Ethanol induced gastric injury is associated with significant production of free radicals, leading to increased lipid peroxidation which causes damage to cell and cell membranes. Accumulation of activated neutrophils in the gastric mucosa may be a source for free radicals. In this study, extract of Curcuma longa exhibited significant protection of rats from ethanol induced mucosal injury. It may be due to its antioxidant effect. Extract of Curcuma longa exerts its beneficial effect by reducing leukotriene antagonist and 5-lipoxygenase inhibitors are capable of inhibiting alcohol and NSAID’s-induced gastric ulceration in rats, so the protection afforded by the extract of Curcuma longa against alcohol induced gastric ulceration.

### DISCUSSION

Curcuma longa has been used in traditional medicine for treating various diseases. The present study supports the traditional use of this plant against gastric problems. Here, extract of Curcuma longa showed gastric mucosal protection comparable to Sucralfate. Pharmacological evaluation of compound UP5145 showed cytoprotective action leading to anti-ulcer property. Free radical injury is a causative factor for ethyl alcohol induced peptic ulcers. In the present study, extract of Curcuma longa showed a significant protection against the experimental ulcers induced by ethyl alcohol. Extract of Curcuma longa on various models suggests its diverse role in ulcer protection, which may include its reported effect on wound healing and as an anti-oxidant. The effect of gastric mucosal cells of patients with gastric ulcer have been considered immature and incapable of producing adequate mucus, which histologically appears to be decreased in the mucus of such patients. Use of natural drugs in gastric ulcers is well documented. Most of these drugs augment the mucosal defensive factors, which are thought to be important for protection of gastric mucosa.

Peptic ulcers are reported to be due to an imbalance between offensive acid-pepsin secretion and defensive mucosal factors like mucus secretion and cell shedding. Extract of Curcuma longa found to have many protective effects on stomach. P-tolylmethylnorcarbinol, a turmeric component, was found capable of increasing bicarbonate and pancreatic enzyme secretion. could also be due to inhibition of 5-lipoxygenase pathway or leukotriene antagonistic activity. Further studies are necessary to confirm these findings.

CONCLUSION
The present study with extract of Curcuma longa revealed that it has significant anti-ulcer properties. Further studies have to be conducted to explain precisely the mechanism of action of this drug.
