TAKOTSUBO CARDIOMYOPATHY: A CASE REPORT
Krishna M. Baradol1, Vijaykumar C. Zalaki2, Mohammed Ghouse Khonkhoni 3, Dharmesh A. Ladhad4

INTRODUCTION: Takotsubo cardiomyopathy or stress-induced cardiomyopathy is a condition caused by intense emotional or physical stress leading to rapid and severe reversible cardiac dysfunction.[1] It was first described in Japan and was subsequently reported in United States and Europe.[2-8] Takotsubo means octopus trap in Japanese.[2] It is also known as left ventricular apical ballooning, ampulla cardiomyopathy and broken heart syndrome.[9] It is generally characterized by transient systolic dysfunction of the apical and/or mid segments of the left ventricle that mimics myocardial infarction (MI), but in the absence of obstructive coronary artery disease.[2-7,10]

CASE HISTORY: (Table 1) First day: A 44 year old labourer presented with three days old bilateral (B/L) traumatic fracture of femur and severe dyspnoea. On examination the patient was restless and in severe respiratory distress. On chest auscultation B/L coarse crepitations were heard all over the lung fields. He was immediately intubated, put on mechanical ventilatory support. All investigations were normal except total leucocyte count: 12, 700/mm.3 Chest X-ray showed B/L basal haziness suggestive of B/L pneumonia. Two dimensional echocardiography (2D ECHO) revealed: pulmonary artery pressure-55 mm Hg; pulmonary embolism was ruled out. He was put on empirical antibiotics. Supportive measures like fluid therapy, feeding, propped up position, position change, suctioning, physiotherapy, thromboprophylaxis, stress ulcer prophylaxis and glycemic control were taken care of throughout. Second day: Patient was extubated. Patient remained stable on third and fourth days.

Fifth day: (Table 1) Patient appeared lethargic, depressed and fearful. He presented with sudden onset chest pain associated with tachycardia and hypotension. 2D ECHO revealed: left ventricle ejection fraction (LVEF) of 34%; gross global hypokinesia of left ventricle (LV) with apical ballooning and no regional wall motion abnormalities. Cardiac enzymes were elevated. Coronary angiography was done which revealed no vascular abnormalities. Probable diagnosis of Takotsubo cardiomyopathy was made. Patient was started on vasoressors (dobutamine, dopamine and noradrenaline infusions). Psychiatric treatment was initiated to counter emotional stress.

Eighth day: (Table 1) General condition was better; stable vitals, no vasoressors. Chest was clear. Chest X-ray showed resolved basal haziness. 2D ECHO revealed normal cardiac function. Both fractures were fixed surgically. Patient continued to remain stable with ongoing supportive therapy and was discharged from hospital on 35th day.

DISCUSSION: A number of features of stress-induced cardiomyopathy, including its association with physical or emotional stress, suggest that this disorder may be caused by diffuse catecholamine induced microvascular spasm or dysfunction, resulting in myocardial stunning, or by direct catecholamine associated myocardial toxicity.[10]
UNLIKE IN PRESENT CASE (44 YEARS), IT IS MORE COMMON IN THE AGE GROUP OF 61-76 YEARS. Triggering factors preceding this syndrome are emotional and physical stress. A wide variety of emotional stressors have been reported, including panic, fear, anxiety, grief and anger. In present case, the patient, being from poor socioeconomic status and lone bread earner of his family, was severely traumatized mentally by the sudden accident, fracture and fear of future.

The clinical presentation of stress-induced cardiomyopathy is similar to that of an acute MI. The most common presenting symptom is acute substernal chest pain, but some patients present with dyspnea, syncope, shock, or electrocardiographic abnormalities.

Our patient presented with chest pain, shock and electrocardiographic changes. Acute complications of stress-induced cardiomyopathy can include heart failure, tachyarrhythmias, bradyarrhythmias, mitral regurgitation and cardiogenic shock. Acute systolic heart failure is the most common complication of stress-induced cardiomyopathy, as in present case, and occurs in ~45% of patients.

Electrocardiographic abnormalities are the most common finding. ST segment elevation was present in 34-56% of patients. Electrocardiography of our patient showed T inversion and nonspecific ST-T changes. Cardiac biomarker levels are usually elevated as in present case.

Echocardiography usually shows the characteristic apical ballooning of the LV. Overall systolic function is reduced, and the reported average LVEF has ranged from 20-49%. These all findings correlate with present case.

All four of proposed Mayo Clinic diagnostic criteria, are required for the diagnosis: 1) Transient hypokinesis, akinesis or dyskinesis of the left ventricular mid segments with or without apical involvement. The regional wall motion abnormalities typically extend beyond a single epicardial coronary distribution.

A stressful trigger is often, but not always present. 2) Absence of obstructive coronary disease or angiographic evidence of acute plaque rupture. 3) New electrocardiographic abnormalities (either ST-segment elevation and/or T wave inversion) or modest elevation in cardiac troponin. 4) Absence of pheochromocytoma or myocarditis. Our case met with all four criteria. Pheochromocytoma and myocarditis were ruled out clinically.

Patients who are in shock should undergo urgent echocardiography to determine if left ventricular outflow tract (LVOT) obstruction is present, which has been described in 13-18% of cases.

Patients without significant LVOT obstruction who are hypotensive due to pump dysfunction as in present case can be treated cautiously with inotropes such as dobutamine and dopamine. Since the condition is potentially caused by catecholamine excess, the impact of sympathomimetics remains to be established. Intra-aortic balloon counterpulsation (IABP) is the preferred therapy when there is marked LV dysfunction associated with severe hypotension or shock. Since IABP was not available at our centre, we managed with inotropes.

In present case, physical stressor was fracture which was fixed. His emotional stressors including panic, fear, anxiety and grief were well tackled by the psychiatrist (psychological and emotional support and counseling).

For patients without intraventricular thrombus but with severe left ventricular dysfunction, anticoagulation is suggested until akinesis or dyskinesis has resolved or for three months, whichever is shorter. In present case we continued anticoagulation till patient mobilization.
 Patients who survive the acute episode typically recover normal ventricular function within one to four weeks. [5, 6, 10] Our patient recovered in three days with normal cardiac function.

**CONCLUSION:** Takotsubo cardiomyopathy is a critical condition presenting with rapid and severe reversible cardiac dysfunction. In the absence of IABP also, severe shock can be managed with cautious use of vasopressors. The success lies in early recognition, proper supportive treatment and meticulous management of physical and emotional stress.
