ABSTRACT

BACKGROUND
Anthropometric measures have been used for screening patients for cardiovascular abnormalities and metabolic syndrome since many years. The measurements generally used are height, weight, waist and hip circumference and their ratio and neck circumference. However, it might not be acceptable for all cultures to agree for such screening. Neck circumference could be an acceptable option for such patients, as it is considered as an index of upper body obesity and correlates positively with changes in blood pressure and other components of metabolic syndrome.

MATERIALS AND METHODS
The study was conducted on patients attending the outpatient department (OPD) for general health check-up at Yenepoya Medical College Hospital among 201 participants above 20 years of age excluding cases with thyroid disorders, any neck surgery and pregnant women. Along with fasting lipid profile, neck circumference was measured in all the participants and parameters evaluated.

RESULTS
On analysis, we found a significant positive correlation between Neck circumference and Cholesterol in males and females with p=0.001 in males and p= 0.02 in females and significant positive correlation between Neck circumference and LDL in males with p<0.001.

CONCLUSION
Studies on similar lines are not available on Indian population. Neck circumference may be used as a simple and time saving screening measure to identify cardiometabolic risk factors like dyslipidaemia in patients.

KEYWORDS
Neck Circumference, Dyslipidaemia, Metabolic Syndrome, Obesity.

cardiovascular disease (CVD) over the next 5 to 10 years. Further, patients with the MetS are at 2- to 4-fold increased risk of stroke, a 3- to 4-fold increased risk of myocardial infarction (MI) and 2-fold the risk of dying from such an event compared with those without the syndrome regardless of a previous history of cardiovascular events. It is important for several reasons.

The metabolic syndrome is a clustering of hyperglycaemia/insulin resistance, obesity and dyslipidaemia. It is defined by the presence of three or more of the following:

1. First, it identifies patients who are at high risk of developing atherosclerotic CVD and type 2 diabetes (T2D).
2. Second, by considering the relationships between the components of metabolic syndrome, we may be able to better understand the pathophysiology that links them with each other and with the increased risk of CVD.
3. Third, it facilitates epidemiological and clinical studies of pharmacological, lifestyle and preventive treatment approaches.

**Risk Factors for Metabolic Syndrome**

- Stress
- Sedentary lifestyle
- Overweight/Obesity
- Smoking
- Diet
- Aging
- Hypertension
- Diabetes mellitus
- Coronary heart disease
- Lipodystrophy

Worldwide prevalence of MetS ranges from < 10% to as much as 84% depending on the region, urban or rural environment, composition (sex, age, race and ethnicity) of the population studied and the definition of the syndrome used. The prevalence of obesity and the metabolic syndrome is rapidly increasing in India and other south Asian countries leading to increased morbidity and mortality due to type 2 diabetes mellitus (T2DM) and cardiovascular disease (CVD).

**Objective**

In the present study, we are attempting to identify the correlation between culturally acceptable anthropometric measure such as neck circumference and fasting lipid profile. This may help identify the candidates who need more detailed evaluation for metabolic syndrome and cardiovascular evaluation.

**MATERIALS AND METHODS**

The study was conducted on patients attending the outpatient department (OPD) for general health check-up at Yenepoya Medical College Hospital. The study was cross-sectional study conducted in 201 participants. Informed written consent was obtained from cases for participation in the study and for conducting investigations. The study was conducted between the period of January 2016 and September 2017.

**Data Collection**

Patients included in this study were all males and females above 20 years of age and cases with Thyroid disorders. Any neck surgery and pregnant women were excluded. Along with fasting lipid profile, neck circumference was measured in all the participants and parameters evaluated.

**Statistical Analysis**

Discrete data was expressed in frequencies and percentages and continuous data was expressed in mean ± SD [Range]. Pearson’s correlation was used to correlate neck circumference with cholesterol and LDL. Data was analysed using the software SPSS version 22.0. P < 0.05 was considered significant.

**RESULTS**

Total of 201 patients were studied, out of which 145 were males and 56 were females. All patients were above 20 years of age, 32% patients were between 41 to 50 years and 21% were between 51 and 60 years of age. Out of 201 patients in this study, 96 patients had Diabetes mellitus, 73 patients had Hypertension and 45 patients had Ischaemic heart disease.

Out of 145 males mean Neck circumference was 36.22 cm, minimal NC was 31.5 cm and maximum NC was 41 cm. Out of 56 females mean Neck circumference was 33.9 cm, minimal NC was 28 cm and maximum NC was 40 cm. Among males, mean cholesterol was 190 and LDL was 118. Among females, mean cholesterol was 193 and LDL was 124.

Data expressed as Mean ± SD [Range].

With Pearson correlation coefficient between Neck circumference and cholesterol and LDL, there was a significant positive correlation between Neck Circumference and Cholesterol in male and females with p < 0.001 in males and p= 0.02 in females and significant positive correlation between Neck circumference and LDL in males with p <0.001.

According to this study, patients with high neck circumference are associated with high cholesterol and high LDL level.
DISCUSSION
In our study conducted at Yenepoya Medical College and Hospital, Mangalore during the period of January 2016 and September 2017, we hypothesised that Neck Circumference is related to dyslipidaemia in Indian population and people with higher value of NC have higher values of fasting lipid profile.

In our study, we measured Neck Circumference and laboratory values including fasting lipid profile (cholesterol, triglyceride, HDL and LDL). The cut-off values for Neck Circumference in males was 37 cm and females was 34 cm and cardiometabolic syndrome diagnosed based on criteria of NCEP ATP III criteria.

Ben Noun et al(4)
Did a study to show Neck circumference as a simple screening measure for identifying overweight and obesity patients. A total of 979 patients were enrolled which include test sample and validation sample, among them 460 were males and 519 were females. This study indicates that NC was associated with age, weight, waist and hip circumferences, waist: hip ratio and BMI for men and women. Thus, a strong association was found between NC and conventional overweight and obesity indexes. NC > 37 cm for men and > 34 cm for women identified subjects with BMI >25.0 kg/m² with 98% to 99% sensitivity for men and 99% to 100% for women, 89% to 92% specificity for men and 98% to 100% for women. These findings indicate that NC can be used as a simple, easy to perform, quick test that can be used to identify overweight or obese patients. Although, NC shows a strong correlation with both overweight and obesity, it is reasonable to consider it as a screening test. Men with NC < 37 cm and women with NC < 34 cm do not require additional evaluation. Patients above these levels require a more comprehensive evaluation of their overweight or obesity status.

Ben Noun et al
Once again in 2004 observed relationship between changes in neck circumference and changes in blood pressure. In this longitudinal cohort study, the study group was comprised of 364 subjects (155 men and 209 women) with no known major medical conditions who were not receiving any medication therapy. They found that changes in systolic BP and diastolic BP correlated positively with changes in NC and other components of the metabolic syndrome.

Liubov et al(5)
Conducted a study to determine a relationship between neck circumference (NC) and risk factors for coronary heart disease by evaluating the components of the metabolic syndrome. A total of 561 subjects (231 males and 330 females) with no major medical conditions and who were not receiving any medications. Study included NC, WC, BMI, BP, FBS and waist: hip ratio. In this study NC was also strongly correlated with SBP, DBP, total cholesterol, LDL-cholesterol, triglycerides, fasting glucose and uric acid levels, NC of > 38 cm in males and > 34 cm in females is correlated positively with factors of metabolic syndrome; therefore, are correlated with the change in risk of cardiovascular disease.

Guang Ran Yang et al(6)
Investigated the association between neck circumference and central obesity, overweight and metabolic syndrome in Chinese individuals with type 2 diabetes. A total of 3185 diabetic subjects were recruited from 15 community health centres in Beijing using a multistage random sampling approach. ROC analysis showed that the area under the curve of NC and central obesity was 0.77 for men and 0.75 for women, respectively. NC > 38 cm for men and > 35 cm for women were the best cut-off points for determining subjects with overweight. A NC > 39 cm in men and > 35 cm in women was the best cut-off point to determine subjects with metabolic syndrome. In present study, NC is positively related with BMI, waist circumference and metabolic syndrome in Chinese individuals with Type 2 diabetes.

Apurva Sawanth et al(4)
Done a clinical study of prevalence of Metabolic Syndrome in Urban India. A total of 560 subjects, who attended the free Cardiac evaluation camp were recruited in the study. The study concluded that prevalence of MS was double in males as compared to females. The study revealed the increased prevalence of MS to be more in 41 - 60 years, suggesting that this group is at risk of developing CAD. It was also found that high percentage prevalence of overweight and obesity was one of the major driving forces in the development of MS. Therefore, early identification of the metabolic abnormalities and appropriate intervention may be of primary importance in populations especially having high prevalence.

Giovanni et al(7)
Investigated to show Neck Circumference as a Predictor of Metabolic Syndrome and Obstructive Sleep Apnoea in Short-Sleeping Obese Men and Women. It was a cross-sectional study of obese men and premenopausal obese women sleeping less than 6.5 hrs. per night. They enrolled 120 individuals (92 women), aged 40.5 ± 6.9 years and body mass index (BMI) of 38.6 ± 6.5 kg/m². Metabolic syndrome was found in 41% and OSAS in 58% (28% had both). A NC of ≥38 cm had a sensitivity of 54% and 58% and a specificity of 70% and 79% in predicting the presence of metabolic syndrome and OSAS, respectively. According to this study, greater NC is associated with OSAS and metabolic syndrome in short-sleeping obese men and premenopausal obese women.

In our study, we have identified that there is a significant positive correlation between Neck Circumference and Cholesterol in males and females, p value of 0.00 in males and p value of 0.02 in females and significant positive correlation between Neck circumference and LDL in males with p value of 0.00.

According to this study, patients with high neck circumference are associated with high cholesterol and high LDL level.

CONCLUSION
According to this study, patients with high neck circumference are associated with high cholesterol and high LDL level. NC may be used as a simple and time saving screening measure to identify cardiometabolic risk factors like dyslipidaemia in patients. This helps in conserving time and resources for patients who are in need of the same in our
present setting. Not many studies are available on this on Indian population and hence further large scale studies would justify and validate the findings of our current study.
