PRESENTATION OF CASE

A 42-year-old male presented with a raised, painless growth over the anterior abdominal wall of more than six years duration. The clinical examination demonstrated a cone-shaped horn-like growth [Figure-1]. After careful and detailed physical examination, the lesion was excised, and abdominal wall defect was repaired with satisfactory result. Specimen was evaluated microscopically. Microscopically, the horn consisted of a mixture of squamous epithelial cells and trichilemmal keratinised debris. The follow-up was uneventful without signs of recurrence. Sebaceous horn or cutaneous horn of anterior abdominal wall is a rare clinical entity. The case of a giant sebaceous horn on the anterior abdominal wall presenting in a 42-year-old male, which was successfully excised, and defect repaired was reported.

Cutaneous horn (Cornu cutaneum) is a relatively uncommon lesion consisting of a projectile, conical, dense, hyperkeratotic nodule, which resembles the horn of an animal.[1] The horn is composed of compacted keratin. Cutaneous horns most frequently occur in sun-exposed parts and are typically found on the face and scalp, but may also occur on the hands, penis, eyelids, nose, chest, neck and shoulder and rarely few cases have been reported where it presents itself on anterior abdominal wall. The cutaneous horns are usually benign; however, malignant or premalignant lesions might be associated with it.[2] Because of their malignant potential, the lesions must always be considered for histopathological evaluation.

DIFFERENTIAL DIAGNOSES

- Common wart.
- Seborrhoeic keratosis.
- Actinic keratosis.
- SCC.
- Keratoacanthoma.
- Bowen’s disease.
- Melanoma (reported rarely).
- Trichilemmal carcinoma.
- Sebaceous adenoma.

DISCUSSION

A cutaneous horn (Cornu cutaneum) is a protrusion from the skin consisting of cornified material resembling an animal horn in miniature. However, the animal horns are composed of superficial hyperkeratotic epidermis, dermis with centrally positioned bone. No such well-formed bone is observed in the human horns. The earliest well-documented case of cornu cutaneum from London in 1588 is of Mrs. Margaret Gryffith, an elderly Welsh woman. However, earliest observations on cutaneous horns in humans were described by the Everard Home in 1791.[3] Farris from Italy first described the well-documented case report with adequate histology of gigantic horn in a man.[4] These horns may arise from a variety of benign, premalignant or malignant epidermal lesions. Most commonly, they are single and arise from a seborrhoeic keratosis lesion.[5] According to a largest study by Yu et al,[6] 61% of cutaneous horns were derived from benign lesions and 39% were derived from malignant or premalignant epidermal lesions. Two other larger studies on cutaneous horn also showed that 23% - 37% of horns were associated with actinic keratosis or Bowen’s disease and another 16% - 20% with malignant lesions.[5,6]

History

Cutaneous horns usually are asymptomatic. Because of their excessive height, they can be traumatised. This may result in inflammation at the base with resulting pain. Rapid growth is common in presentation.

Physical Examination

Cutaneous horns can occur anywhere on the body. However, the more typical distribution is on sun-exposed areas, particularly the face, pinna, nose, forearms and dorsal hands. Thirty percent of cases have been seen to arise on the scalp and upper face. They are most commonly a solitary lesion.

It is a hyperkeratotic papule with the height greater than half the width of the base. Usually, a cutaneous horn is several millimeters long, but they can grow to be quite large, up to 25 cm in some cases and 36 cm diameter in historic cases.
PATHOLOGICAL DISCUSSION
The important consideration in these cases is not the horn, but the underlying pathology which may be benign (Seborrheic keratosis, viral warts, histiocytoma, inverted follicular keratosis, verrucous epidermal nevus, molluscum contagiosum, etc.), premalignant (Solar keratosis, arsenical keratosis, Bowen's disease) or malignant (Squamous cell carcinoma, rarely basal cell carcinoma, metastatic renal carcinoma, granular cell tumour, sebaceous carcinoma or Kaposi's sarcoma.[7] Histopathological examination, specially of the base of the lesion[1][8][9] is necessary to rule out associated malignancy and full excision and reconstruction is the treatment of choice. The cutaneous horns are predominantly benign lesions; however, possibility of malignant potential should always be kept in mind.

Histologic Findings
The horn is composed of compact hyperkeratosis, which may be either orthokeratotic or parakeratotic in nature as shown in the image below.

DISCUSSION ON MANAGEMENT
Treatment recommendation is contingent upon the type of lesion at the base. In order to rule out a malignancy, it is essential to perform a biopsy of the lesion that includes the base of the horn. In case of benign lesions at the base of the horn, the biopsy is both diagnostic and therapeutic.

Excise malignancies with appropriate margins. Patients discovered to have horns with an underlying squamous cell carcinoma also should be evaluated for metastasis.

Local destruction with cryosurgery is the first-line treatment for verruca vulgaris, actinic keratosis and molluscum contagiosum. Benign lesions do not require any further therapy after the diagnostic biopsy.

FINAL DIAGNOSIS
Anterior Abdominal Wall Sebaceous Horn.
