ABSTRACT

BACKGROUND

Lung malignancy was typically described as a disease of industrial revolution and urbanisation, but with rampant tobacco abuse it reached epidemic proportions. The disease was typically confined to middle aged to elderly smokers, but the changing demographics and habits have shown an increasing trend of lung malignancy in females and non-smokers. Even after long and laborious years of research, lung malignancies even today beseech curative treatment.

MATERIALS AND METHODS

The present study is a prospective, hospital based, descriptive study. We use cell block method for diagnosis of lung cancers and by analysing history of patients we prepared demographic data.

RESULTS

We conducted a study of diagnosis of lung malignancy by cell block method. We studied a total of 75 samples from clinically suspected patients with lung malignancies. We found 48 patients with lung malignancy. We found in our study incidence of lung malignancy is more in Males (66.66%) than in Females (33.33%) due to smoking pattern and occupational exposure to hazardous carcinogens. Lung malignancy most commonly affects older population, people with age more than 50 are at more risk. Patients with age group 51 - 60 years (56.25%) are most affected. People living in rural (70.83%) areas are at more risk of developing lung cancer as compared to people living in urban (29.16%) areas due to smoking habits and more exposure to environmental carcinogen. Labourers (41.66%) are most affected population than other occupation due to occupational exposure to industrial carcinogens. People having history of smoking (79.16%) are more prone to develop lung malignancy than non-smokers (20.83%). Bidi (78.94%) is the most common indigenous smoking pattern used by patients, as it is easily available and cheap.

CONCLUSION

By studying demographic profile, we conclude that environmental pollutants and smoking carcinogens made people more prone to lung cancers than normal people.

KEYWORDS

Cell Block, Lung Malignancies.

Aims and Objectives

To study demographic profile of patients with lung malignancies.

MATERIALS AND METHODS

Place- Tertiary Care Hospital.

Study Population

Patients admitted under Department of Pulmonary Medicine and Department of Medicine with features suggestive of lung malignancies, e.g. haemoptysis, recurrent pleural effusion, cervical and mediastinal lymphadenopathy and patients presenting with undiagnosed lung masses on radiology.

Study Design

The present study is a prospective, hospital based, descriptive study.

Study Period

18 months from 01-01-2013 to 30-06-2014.

Inclusion Criteria

Patients admitted under Department of Pulmonary Medicine and Department of Medicine with features suggestive of lung...
malignancies e.g. Haemoptysis, Recurrent pleural effusion, Cervical and Mediastinal lymphadenopathy and Patients presenting with undiagnosed lung masses on radiology.

Exclusion Criteria
Diagnosed patients with lung malignancies are excluded from the study.

Methodology/ The Study Variables-
Socio-Demographic Characters-
1. Name.
2. Age.
3. Sex.
5. Residence.

Clinical History
1. Presenting Complaints.
2. Any Hospitalisation in past.
3. Past History.
4. Family History.
5. Chronic Illness.
6. Physical Examination: General and Systemic examination.

Laboratory Parameters
2. Liver Function Test.
4. Pleural Fluid Biochemistry: Glucose, Protein, LDH.

Radiological Investigations
1. X-ray chest.
2. Ultrasonography of chest.

All Patients Suspicious for Lung Malignancy were Evaluated
- After detailed clinical and personal history, general and clinical examination was noted.
- Radiological examinations like X-ray chest, CT-chest and USG chest were also taken into consideration.
- Patients were clinically suspected for lung malignancy, classified according to nature of sample received as-

1. Patients Presenting with Pleural Effusion-
After informed and written consent, under strict aseptic precautions pleural fluid tapping was performed in wards by clinicians and 10 mL of pleural fluid was sent to cytology lab in EDTA anticoagulated bulb within 2 hours of tapping. The samples were immediately processed by conventional cytological smear preparation and on cell block preparation if found positive or suspicious for malignancy, hence same sample was evaluated for comparative study.

Other samples used are-
2. USG-guided FNAC of Lung Mass-
Tissue sample obtained by FNAC were also processed, both on routine cytology slide and cell block method.

3. Bronchoalveolar Lavage (BAL) Cytology-
Tissue sample obtained by BAL were also processed, both on routine cytology slide and cell block method.

Technique of Conventional Smear Preparation-
5 mL pleural fluid sample centrifuged at 2500 rpm for 15 mins, then a thin smear was prepared from sediment. Cytological smear was stained by haematoxylin-eosin stain.

Image 1. H and E Stained Slide of Conventional Smear

Haematoxylin-Eosin Staining Method for Conventional Method
After making smear from sediment on slide, slide is fixed in methanol after that slide dip in Haematoxylin for 15 mins, then slide washed with tap water and dip in eosin for 1 min. Slide mount with DPX and observed under microscope.

Technique of Cell Block Preparation
5 mL pleural fluid, then add 5 mL 10% Alcohol-Formalin, keep for 1 hour, then centrifuge for 2500 rpm for 15 mins. Discard supernatant and again add 3 mL 10% alcohol-Formalin for 24 hrs. to cell button. After overnight fixation scoop out cell button and process as routine histopathology specimens.

RESULTS
Observations
The interpretation of conventional smear and cell block.

The Samples were studied in detail, taking into account the available Clinical Data, various Investigation Reports and Microscopic Details. The Samples were categorised as-
1. Positive for Malignancy (PFM).
2. Suspicious for Malignancy (SFM).
3. Negative for Malignancy (NFM).

The Morphological Criteria that were taken into Account included the-
1. Celularity.
2. Arrangement of the cells (acini, papillae and cell balls).
3. Cytoplasmic and the nuclear details of suspicious or malignant cells.
4. Presence of inflammatory cells like lymphocytes, polymorphs and mesothelial cells.
All these criteria were put together and they were used for the categorisation of the sample. The cytomorphological characters were studied in detail to identify the malignancy. A comparative evaluation of the CS versus the CB techniques was conducted.

Interpretation of Conventional Smear
1. Positive for Malignant Cells (PFM).
2. Suspicious for Malignancy (SMF).
3. Negative for Malignancy (NFM).

Image 2. Low Power (10x) H and E- Pleural Fluid Cytology

Smear study shows presence of Round-to-Oval atypical cells arranged in groups against inflammatory and mucinous background.
Diagnosis given- Suspicious for Malignant Cells (SFM).

Image 3. Low Power H and E- Pleural Fluid Cytology on Conventional Smear

Smear study shows scattered round-to-oval tumour cell over background of RBCs and inflammatory cells.
Diagnosis was given- Suspicious of Malignancy (SFM).
(Adv.: Cell Block Cytology).
Possible-Adv.: Cell Block Cytology).

Image 4. High Power H and E Pleural Fluid Cytology

Smear study shows presence of round-to-oval tumour cells having hyperchromatic, pleomorphic nuclei and scant cytoplasm against haemorrhagic background.
Diagnosis given- Positive for Malignant cells (PFM).

Image 5. Pleural Fluid Cytology- High Power H and E
Smear Study shows Atypical Cells with Eccentric Nuclei with Moderate Amount of Cytoplasm

Image 6. Pleural Fluid Cytology

High power H and E stained-smear study shows many large cells having hyperchromatic pleomorphic nuclei and scanty cytoplasm on necrotic background material.
Diagnosis was given- Positive for Malignant cells (PFM)-typing not possible.

Diagnosis given was Negative for Malignancy (NFM)/Inflammatory Smear.

Interpretation of Cell Block Cytology
Smear which are positive and suspicious for malignancy are processed on cell block. Due to better architectural pattern, cellularity, greater nuclear and cytoplasmic details typing of lung malignancies were possible. Smears were interpreted as-
Positive for Malignant Cells
And given further histological typing. E.g. Adenocarcinoma of lung, squamous cell carcinoma lung, small cell carcinoma lung etc.

Image 8. Low Power H and E: Cell Block Cytology from Pleural Fluid Sediments Smear shows Round-to-Oval Tumour Cells Arranged in Acinar-Glandular Pattern

Positive for Malignant Cells (PFM) s/o Adenocarcinoma Lung

Positive for Malignant (PFM) cells- squamous cell carcinoma lung.

RESULTS
In this study, 75 cases were studied during January 2013 to June 2014. All samples of patients with suspected lung malignancies are processed on conventional smear and cell block.

The following Results were made with regard to-

<table>

Table 1. Distributions of Cases with Lung Malignancies according to Sex (n= 48)

Table 10 shows Male (66.66%) patients are more affected than female (33.33%) patients with lung malignancy. Male-to-Female ratio is 2: 1.

Males are more affected than females. This is due to smoking habits, exposure to carcinogens at work place.

**Table 7. Form of Smoking used by Patients Addicted with Lung Malignancies (n= 38)**

Above table shows that Bidi is the most common form of tobacco smoking seen in 30 (78.94%) patients followed by cigarette (18.42%) smoking and Hukka smoking (2.63%).

Bidi is easily available and cheap; hence, it may be the commonest form of smoking.

**Graph 5. Showing Distribution of Patients according to Form of Smoking**
DISCUSSION

In this study, 10% Alcohol-Formalin is used as a fixative for modified cell block preparation. By this better cellularity is obtained compared to conventional smear, as formalin minimizes cell loss by forming protein cross links.

*Table 9. Comparative Study of Male: Female Ratio of Patients with Lung Malignancy in Different Studies*

In study by Bahera D et al 2004 found that Male: Female ratio of patients with lung malignancy ranged from 5.76 to 6.67: 1.

Prabhat et al 2013, ratio was found to be 4.6: 1.

Sanjeetkumar et al 2013, Male-to-Female ratio found to be 1.09: 1.

In our study, we also found ratio of 2: 1. This is due to smoking habits in males and more exposure to occupational carcinogen at work place.

Our study is comparable with Sanjeetkumar et al 2013.

*Table 11. Comparative Study of Clinical Presentation of Patients with Lung Malignancy*

NR: Not Reported.

In study done by Behera D et al 2004 found that Cough with Expectoration (88%) was the most clinical presentation of patients with Lung Malignancy followed by haemoptysis (69.2%) and chest pain (52.2%).

Study done by Prabhat et al 2013 (57.03%) and Sanjeetkumar et al 2013 (36.6%) also found Cough with Expectoration was the most common clinical presentation.

In our study, we also found Cough with Expectoration (72.91%) is the most common clinical presentation followed by chest pain and dyspnoea (62.50%), then haemoptysis (52.08%) and fever (20.83%).
Study done by Behera et al. 2004, found that farmers (30.95%) were most commonly affected occupation followed by labourers (24.15%) than others in patients with lung malignancy.

In our study, we found labourers (41.66%) are the most common affected occupation followed by farmers (29.16%) and housewives (25%).

**Table 12. Comparative Study of Most Common Occupation of Patients with Lung Malignancy**

Study done by Prabhat et al² 2013, found that Bidi (55.25%) is the most common form of smoking associated with patients with lung malignancy followed by cigarette smoking (28.45%).

In our study, we also found Bidi (78.94%) is the most common form of smoking used by patients with lung malignancy followed by cigarette smoking (18.42%).

**Summary**

We conducted a study of diagnosis of lung malignancy by cell block method, we study a total of 75 samples from clinically suspected patients with lung malignancies. We found 48 patients with lung malignancy. We found in our study-

1. Incidence of lung malignancy is more in Males (66.66%) than in Females (33.33%) due to smoking pattern and occupational exposure to hazardous carcinogens.
2. Lung malignancy most commonly affects older population. People with age more than 50 are at more risk. Patients with age group 51 - 60 years (56.25%) are most affected.
3. People living in rural (70.83%) areas are at more risk of developing lung cancer as compared to people living in urban (29.16%) areas due to smoking habits and more exposure to environmental carcinogen.
4. Labourers (41.66%) are most affected population than other occupation due to occupational exposure to industrial carcinogens.
5. People having history of smoking (79.16%) are more prone to develop lung malignancies than non-smokers (20.83%).
6. Bidi (78.94%) is the most common indigenous smoking pattern used by patients, as it is easily available and cheap.
7. Right lung (68.75%) tend to involve more than left lung (31.25%) in cases of lung malignancy.
8. Due to changing pattern, filtered smoke cigarettes in market increased in number of female smokers and more exposure of females to household environmental carcinogens. Adenocarcinoma (75%) is the most common histological subtype found.

**CONCLUSION**

1. Cell block technique by using 10% alcohol-formalin as a fixative is simple, inexpensive and does not require special training and instrument.
2. Morphological features are better appreciated by cell block method as compared with conventional smear.
3. Multiple sections can be obtained if required for special stain and immunohistochemistry (IHC) studies.
4. Sensitivity of malignant cases by cell block method was significantly increased as compared with conventional smear method.
5. With increasing prevalence of smoking, lung cancer has reached epidemic proportions.
6. In addition to smoking, occupational exposure to carcinogens, indoor air pollution and dietary factors have presently implicated in causation of lung malignancy.
7. Various modalities for early detection through screening are being investigated. Majority of patients have locally advanced or disseminated disease at presentation and are not candidates for surgery.
8. Chemotherapy applied as an adjuvant with radiation improves survival and quality of life, hence appropriate histological diagnosis is needed for proper treatment.
9. New anticancer drugs, which have emerged during the last decade have shown an improved efficacy in treatment of lung malignancy.
10. In view of our large population, the burden of lung cancer will be quite enormous in India.
11. Drastic measures aimed at discouraging people from smoking must be taken to reduce the morbidity and mortality due to lung malignancy.
