ABSTRACT

BACKGROUND

Dexmedetomidine, a highly selective α2 adrenergic agonist and Midazolam, a benzodiazepine derivative both modulate spinal analgesia by different mechanisms. We compared Dexmedetomidine and Midazolam as an adjuvant to hyperbaric Bupivacaine in subarachnoid blockade to evaluate the onset and duration of motor and sensory block, post-operative analgesia, hemodynamic changes and adverse effects.

MATERIALS AND METHODS

In this randomized controlled trial, sixty female patients aged 18 – 65 years of ASA grade 1 and 2, randomly allocated into two groups (30 in each group), posted for total abdominal hysterectomy, were studied. Group D received 12.5 mg of hyperbaric Bupivacaine plus Dexmedetomidine (10 µg) in 1 ml of normal saline. Group M received 12.5 mg hyperbaric Bupivacaine plus Midazolam (2.5 mg) in 1 ml of normal saline. The two groups were compared with respect to onset of sensory and motor block, regression time of sensory and motor block, rescue analgesia, hemodynamic data and adverse effects. Sample size was taken for convenience. Statistical Package for Social Science (SPSS 18.0 evaluation version) was used for the analysis to obtain the data and Microsoft Word, Excel have been used to generate graphs, tables, etc. Results on continuous measurement are presented on Mean ± SD and continuous data is analysed. Significance is assessed at 5% level of significance.

RESULTS

Group D patients showed a significantly prolonged sensory and motor block than Group M patients. The sensory regression time to S1 was (324.67 ± 27.26 min) in Group D and (254.00 ± 20.44 min) in Group M. The time of motor block regression to reach Bromage 0 was (314.33 ± 23.44 min) in Group D and (212.33 ± 11.35 min) in Group M. Rescue analgesic time was significantly prolonged in Group D (419.33 ± 21.80 min) as compared to Group M (271.33 ± 30.14 min).

CONCLUSION

Dexmedetomidine (10 mcg) as an adjuvant to Bupivacaine in subarachnoid blockade is associated with longer sensory, motor block and longer duration of analgesia in comparison to Midazolam (2.5 mg) with a comparable incidence of side effects.

KEY WORDS

Spinal Anaesthesia, Bupivacaine, Dexmedetomidine, Midazolam.

BACKGROUND

Spinal Anaesthesia is one of the most commonly used techniques for lower abdominal surgery as it is very economical and easy to administer with the advantage of providing surgical anaesthesia. However, post-operative pain management is a problem because spinal anaesthesia using local anaesthetics alone is associated with relatively short duration of action and thus early intervention is required in the post-operative period.

Different adjuvants such as Opioids, magnesium sulphate, clonidine, and others have been used to prolong the effect of spinal anaesthesia.1,2

Dexmedetomidine, a highly selective α2 adrenergic agonist, when used as an adjuvant to spinal Bupivacaine provides a good quality of analgesia with fewer side effects.3,4

Midazolam, a benzodiazepine derivative has been used for potentiating the analgesic effect of local anaesthetic induced neural blockade.5,6 This study was designed to assess the effect of Dexmedetomidine, and Midazolam added to hyperbaric Bupivacaine intrathecally on onset and duration of sensory and motor block, duration of analgesia and any side effects in patients undergoing total abdominal hysterectomy.

MATERIALS AND METHODS

After obtaining approval from the hospital ethical committee along with written and informed consent, 60 adult female patients belonging to ASA class I and II aged 18-65 years posted for total abdominal hysterectomy under subarachnoid blockade were enrolled in this randomized controlled trial.

Sample Size taken for Convenience

This study was carried out in the Department of anaesthesia at Kempegowda Institute of Medical Science and Hospital, Bangalore from September 2016 to August 2017. A
computer-generated random allocation sequence was obtained, and the patients were allocated based on that list. All patients were randomly divided into two groups with 30 patients in each group. Patients with history of Ischemic heart disease, hypertension, allergy to the study drug, dysrhythmias or any contraindication for spinal anaesthesia and failure of spinal block were excluded from the study.

All patients advised fasting for 6 hours and received Pantoprazole 40 mg the night before surgery and were familiarized with visual analogue scale (VAS).

On arrival to the operation room, pulse oximetry, non-invasive blood pressure and electrocardiogram were monitored. IV Line was secured and infusion of 500 ml of lactated Ringer’s solution was given. Under all aseptic precautions patients back painted and draped in sitting position. At L3-L4 intervertebral space, using 26G Quincke spinal needle lumbar puncture was done.

**Group D (30 Patients)**

Received 12.5 mg hyperbaric Bupivacaine (2.5 ml) plus Dexmedetomidine (10 µg) in 1 ml of normal saline.

**Group M (30 Patients)**

Received 12.5 mg hyperbaric Bupivacaine plus Midazolam (2.5 mg) in 1 ml of normal saline.

After intrathecal injection, Patients were positioned in supine position and oxygen 5 l/min was given through a face mask. The anaesthesiologist performing the block was blinded to the study drug and recorded the intraoperative data. The onset of sensory and motor block, highest level of sensory block, time to complete motor block recovery and duration of spinal anaesthesia were recorded. The sensory block onset time is defined as time interval between injection of drug and the absence of pain at T10 dermatome assessed by sterile pinprick every 2 min till T10. On achieving T7 sensory blockade, procedure was started. Pin prick test was done every 10 min. until the point of 2 segment regression of the block was observed. Modified Bromage scale was used to assess the motor level:

- **Grade 0:** Patient able to move ankle, knee and hip.
- **Grade 1:** Patient able to move the knee and ankle but is unable to move the hip.
- **Grade 2:** Patient is able to move the ankle but is unable to move the hip and knee.
- **Grade 3:** Patient unable to move the ankle, knee and hip.

Hemodynamic data were recorded at 5, 10, 15, 20, 25, 30 min and subsequently every 30 min. The incidence of nausea and vomiting and sedation were recorded. Sedation was assessed by modified Ramsay sedation scale:

1. Patient agitated, anxious and restless.
2. Patient is oriented co-operative and tranquil.
3. Patient responds to verbal commands while sleeping.
4. Patient exhibits brisk response to light loud noise or glabellar tap while sleeping.
5. Patient sluggishly responses to light loud noise or glabellar tap while sleeping.
6. Patient does not respond to light glabellar tap or loud noise while sleeping.

Sensory and motor block regression time was recorded in a post anaesthesia care unit (PACU) along with the vital signs and Visual analogue scale (VAS) scores. Any patients showing VAS more than or equal to 3 was considered as rescue analgesic requirement and Inj. Diclofenac intramuscularly was given.

**Statistical Analysis**

Statistical Analysis was done using student’s t test, Leven’s t test.

Significance is assessed at 5% level of significance. P Value < 0.05 was considered statistically significant. Statistical package for social science (SPSS 18.0 evaluation version) was used for the analysis to obtain the data and Microsoft word, Excel have been used to generate graphs, tables, etc. Results on continuous measurement are presented on Mean ± SD.

**RESULTS**

The two groups were found to be comparable with respect to age, height, weight and ASA physical status (Table 1). The sensory and motor block characteristics and time for regression are summarized in (Table 2).

**Table 1. Demography**

**Table 2. Characteristics of Block**

The onset time of block, both sensory and motor block was found to be similar in both groups. There was no statistically significant difference between the two groups with respect to highest level of block achieved.
DISCUSSION

Various adjuvants such as clonidine, fentanyl and others have been studied to prolong the effect of spinal anaesthesia. Dexmedetomidine is an selective α2 adreno receptor agonist which has ten times higher affinity for α2 adreno receptor than Clonidine. Dexmedetomidine as an adjuvant to hyperbaric Bupivacaine in spinal anaesthesia prolongs the sensory block by inhibiting the release of C-fiber transmitters by hyper polarization of dorsal horn post synaptic neurons.8,9,10 The prolongation of motor block by α2 adreno receptor agonist results from binding these agonists to motor neuron in the dorsal horn of the spinal cord.11 α2 adreno receptor agonist given spinally have anti-nociceptive action for both somatic and visceral pain.

Midazolam, a benzodiazapine derivative mediates spinal analgesic effect by GABA receptor complex present in the dorsal horn of the spinal cord.12 Intrathecal Midazolam also has anti nociceptive effect mediated via spinal opioid receptors.13

This Randomized controlled trial was conducted to find out the comparative effect of intrathecal Dexmedetomidine and Midazolam as an adjuvant to hyperbaric Bupivacaine in patient undergoing total abdominal hysterectomy. We found that there was prolonged sensory, motor block and post-operative analgesia as compared to Midazolam group.
Kanazi et al\(^{13}\) found that addition of Bupivacaine (12 mg) in spinal anaesthesia with a dosage of Dexmedetomidine (3 \(\mu\)g) produced significantly prolonged sensory and motor block than Bupivacaine alone, which is in par with our present study.

Rajni Gupta et al\(^{15}\) in the study the effect of adding Dexmedetomidine v/s fentanyl to intrathecal Bupivacaine concluded that Dexmedetomidine produces more prolonged motor and sensory block as compared with fentanyl. In our present study, Dexmedetomidine group we found prolonged duration of both sensory and motor blockade, stable hemodynamic conditions and good patient’s satisfaction. The significant adverse effect was bradycardia and hypotension. In our study hypotension and bradycardia was more in the Dexmedetomidine group than in Midazolam group, but it was not statistically significant.

Shukla et al\(^{16}\) studied the effect of adding Dexmedetomidine v/s Midazolam to hyperbaric Bupivacaine in spinal anaesthesia and found that Dexmedetomidine produced more better motor and sensory block when compared with Midazolam. Time to rescue analgesia was significantly longer in Dexmedetomidine group (380.0 \(\pm\) 18.0 min) when compared to Midazolam group (220.1 \(\pm\) 14.8 min). We had similar result in our study.

Samantaray et al\(^{17}\) studied 60 patients and found time to 2 segment regression and time to 51 segment regression was significantly longer in Dexmedetomidine group in comparison to Midazolam group. Our study showed us similar results regarding regression time of sensory analgesia.

Choudhary et al\(^{18}\) in their study showed Dexmedetomidine group had highest incidence of hypotension and bradycardia compared to Midazolam group. Our study had similar results, but it was not statistically significant. Number of patients sedated was more with Dexmedetomidine group than Midazolam group, but it was not statistically significant.

**CONCLUSION**

Intrathecal Dexmedetomidine (10 mcg) is more efficient than Midazolam (2.5 mg) as an adjuvant to spinal Bupivacaine for total abdominal hysterectomy. It is associated with longer motor and sensory block and provides excellent quality of post-operative analgesia as compared to Midazolam without any significant hemodynamic instability.
