ABSTRACT

BACKGROUND

MDR tuberculosis remains a leading chronic infection of lung and responsible for significant morbidity and mortality throughout the world and in India also. Depression is also a disorder of major public health importance in terms of its prevalence and the suffering, dysfunction, morbidity and economic burden. Depression and MDR tuberculosis co-exists, because of physical changes from the illness trigger the depression resulting in vicious cycle. So, it is very important to establish the prevalence of depression in MDR tuberculosis. To the best of our knowledge, very little is known about depression in MDR tuberculosis patients.

The objective of this study is to find out the prevalence of depression among newly diagnosed MDR tuberculosis patients before the start of Category-IV treatments.

MATERIALS AND METHODS

This was a cross-sectional study conducted in Department of Respiratory Diseases, GMC, Kannauj (India). A total of 130 MDR-TB patients were included in the study, which were enrolled for treatment in this unit from January 2017 till June 2017 and assessed at the time of registration for depression. Hamilton depression rating scale (HAM-D) was used to assess depression among MDR-TB patients.

RESULTS

One hundred and thirty patients with MDR tuberculosis were enrolled during the study period. There were 93 males (71.5%) and 37 (28.4%) females. The mean age of study subject was 29.45 ± 14.49 years with a male-to-female ratio of 2.5:1. Depression was not found in 6 (4.62%) patients, whereas 124 (95.3%) of the study participants were classified as depressive on the HAM-D scale. 65 patients (50%) had mild depression, 26 patients (20%) had moderate depression and 33 patients (25.3%) were diagnosed with severe depression.

CONCLUSION

Depression is a very important negative factor to treatment adherence and it is important to diagnose and treat depression in time to get the desired results of TB treatment.

KEYWORDS

Depression, Multi-Drug Resistance, Tuberculosis.

BACKGROUND

Tuberculosis is a chronic infectious disease caused predominantly by Mycobacterium tuberculosis and India accounts for one-fourth of the global TB burden (i.e. 2.2 million out of 9.6 million new cases annually).1

Multi-drug resistant TB (MDR-TB) is defined as M. tuberculosis resistant to isoniazid and rifampicin with or without resistance to other drugs. Data from studies conducted by NIRT (erstwhile TRC) and NTI, have found MDR-TB levels of 1% to 3% in new cases and around 12% in re-treatment cases.2-3 RNTCP has recently undertaken three community-based state level drug resistance surveillance (DRS) studies in Gujarat, Maharashtra and Andhra Pradesh. These surveys have been conducted as per a common generic protocol based on internationally accepted methodology and have estimated the prevalence of MDR-TB to be about 3% in new cases and 12%-17% in re-treatment cases.4

Common mental disorders (CMDs) including depression, anxiety disorders and substance use disorders are a huge burden affecting nearly 10.0% of the population.5 Depression, among the other psychiatric morbidities, has a lifetime prevalence of 10%.6 It has a point prevalence of 2.3% to 4.9% in the general population.7 Comorbidity of TB and depression is common.6-9 The prevalence of comorbid depression with a chronic physical condition ranges between 25% and 33%. The risk increases with the severity of the illness10 and this
frequently presents a management challenge to physicians. The cause of the comorbidity remains unclear. Chronic psychogenic and somatic pain, frequent hospital admissions and hospital dependency are factors related to depression among persons with chronic pulmonary diseases. Furthermore, it has been reported that 30% of patients with moderate respiratory failure have depression.

Psychiatric complications are commonly associated with MDR-TB, both at baseline and due to Second Line Drug (SLD) use. The frequency of psychiatric disorders associated with MDR-TB treatment varies from 6.2% to 22%.

The baseline mental health characteristics of patients may determine the development of subsequent psychiatric conditions. A mental health assessment before MDR-TB treatment initiation may thus assist in better management of psychiatric illnesses and improve treatment outcomes.

Depression may also adversely affect the compliance to treatment and result in default which in turn may have serious consequences of treatment failure and further extension in drug resistance. Depression may be a very important negative factor to treatment adherence for patients on tuberculosis treatment.

Despite the high prevalence of MDR-TB in India, there is a dearth of information on the prevalence of depression among patients suffering from MDR-TB, hence the justification for this study.

MATERIALS AND METHODS

Study Design
This was a cross-sectional study conducted to describe frequency of depression and other associated factors among MDR-TB patients at baseline (at the time of registration for MDR-TB treatment).

Subjects
From a total of 195 patients, only 130 MDR-TB patients were interviewed during the study period, which were enrolled for treatment in this unit from January 2017 to April 2017. Convenient sampling technique was used for data collection.

Data Collection
Patient interviews were conducted by one data collector using a structured questionnaire. The structured questionnaire was designed to assess socio-demographic factors such as marital status, socioeconomic status, age, gender, duration of past treatment; weight, monthly income, residence, comorbidity and patient’s contact status.

All registered MDR-TB patients were assessed individually. After developing rapport with each patient, psychological assessment was performed by a clinical psychologist using diagnostic and statistical manual of mental disorders, Fourth Edition (DSM-IV-TR) criteria for depression and Hamilton Depression Rating scale. Every patient was assessed at the time of registration.

Tools/ Hamilton Depression Rating Scale Subsequent
Hamilton depression rating scale (HAM-D) was used to assess depression among MDR-TB patients. The HAM-D scale consists of 20 questions according to the criteria of major depression as per the diagnostic and statistical manual of mental disorders, Fourth Edition, Text Revision (DSM-IV-TR). Total score ranges from 0 to 57 and indicate the severity of depression. In addition, the scoring is based on the first 17. It generally takes 15 - 20 minutes to complete the interview and score the results. It is a valid and reliable scale. Descriptive statistics were used to describe the data, i.e. mean and frequency along with percentages for categorical variables.

Ethical Approval
The study was approved by Research and Ethics Committee of the Institution, Kanpur, India.

RESULTS
A total of 130 MDR-TB patients were recruited for the study. Out of 130 patients, 93 (71.5 %) were male and 37 (28.5%) were female patients. The majority of subjects were married 71 (54.6%), while unmarried were 54 (41.5%). The mean age of study subject was 29.45 ± 14.49 years with a male-to-female ratio of 2:5:1. Most of the patients 89 (68.4%) had history of past TB treatment for more than one year, while duration of less than one year was 41 (31.5%). Patients belonging to rural area were 80 (61.5%) and patients of urban area were 50 (38.5%). Depression was not found in 6 (4.62%) patients, whereas 124 (95.3%) of the study participants were classified as depressive on the HAM-D scale, 65 patients (50%) had mild depression, 26 patients (20%) had moderate depression and 33 patients (25.3%) were diagnosed with severe depression. The prevalence of depression was assessed in each group. Details given in Table 1.

They reported that Depression was present in 45.5% of tuberculosis patients and among whom 45.8% were moderately and severe depression were 13.6%, 11.4% and 20.5% respectively. The percentage of mild, moderate and severe depression in the present study are 50%, 20% and 25.38% respectively. Basu G et al had done an observational study in a DOTS clinic to know the prevalence of depression in 110 tuberculosis patients. The Patient Health Questionnaire-9 was used to assess the depression and its severity. They concluded that 62% of the patients were depressed and majority of them belonged to the mild and moderate depression and 5.5% patients were severely depressed. The results of the above-mentioned study are comparable to the present study and majority of them have mild depression. Mrinalini Das et al had done a study to address the baseline psychiatric conditions of 45, HIV-infected MDR-TB patients with the Patient Health Questionnaire-9 (PHQ-9) tool. Of these seven (16%) patients had depressive symptoms, while 38 did not have baseline depressive symptoms. The results in the present study are on higher side and the percentage of normal patients is 4.62%. A study was done to assess the prevalence of depression in 222 tuberculosis patients and its relationship with regard to socio-demographic factors, disease characteristics, treatment factors and HIV infection. A pre-designed questionnaire, the Kessler which is prepared to be used for the rating depression and anxiety. This study has shown that 19.82% of tuberculosis patients were cases of depression and depression cases were 100% in older age group.

Islam A et al had done a study on 108 patients of tuberculosis to evaluate pattern of psychiatric illness among tuberculosis. They reported that depressive illness was the commonest (39.83%, n= 43) and others were anxiety (30.5%), somatiform (10.1%), psychotic spectrum disorder (8.3%), personality disorder (6.4%) and substance use disorder (3.1%). The prevalence of depression in TB patients obtained in the present study is on the higher side and only depression parameter is analysed. Moussavi et al have done a study on 108 patients of tuberculosis to evaluate pattern of psychiatric illness among tuberculosis. They reported that depressive illness was the commonest (39.83%, n= 43) and others were anxiety (30.5%), somatiform (10.1%), psychotic spectrum disorder (8.3%), personality disorder (6.4%) and substance use disorder (3.1%). The prevalence of depression in TB patients obtained in the present study is on the higher side and only depression parameter is analysed. Moussavi et al have done a study on 108 patients of tuberculosis to evaluate pattern of psychiatric illness among tuberculosis. Moussavi et al have done a study on 108 patients of tuberculosis to evaluate pattern of psychiatric illness among tuberculosis. They reported that depressive illness was the commonest (39.83%, n= 43) and others were anxiety (30.5%), somatiform (10.1%), psychotic spectrum disorder (8.3%), personality disorder (6.4%) and substance use disorder (3.1%). The prevalence of depression in TB patients obtained in the present study is on the higher side and only depression parameter is analysed. Moussavi et al have done a study on 108 patients of tuberculosis to evaluate pattern of psychiatric illness among tuberculosis. They reported that depressive illness was the commonest (39.83%, n= 43) and others were anxiety (30.5%), somatiform (10.1%), psychotic spectrum disorder (8.3%), personality disorder (6.4%) and substance use disorder (3.1%).

Eighteen (27.7%) of the total patients had depression, comprising 14 (21.5%) with mild depression and four (6.2%) with moderate depression. This study also highlighted that 47 patients did not have the symptoms of depression. In the present study, 6.45% patients did not have the symptoms of depression. Ige OM et al had done a study to determine the prevalence of depression in 85 tuberculosis patients in comparison with non-tuberculosis controls, and its correlation with disease pattern with the help of GHQ-12. They reported that Depression was present in 45.5% of patients and 13.4% of controls (P < 0.001). The prevalence of mild, moderate and severe depression were 13.6%, 11.4% and 20.5% respectively.

The relationship between depression and chronic diseases can be bidirectional and people who suffer from chronic diseases report worse self-rated health as shown by Alves and Rodrigues through a population-based study conducted in Sao Paulo. When TB and depression coexist, the risk for developing comorbidities, suffering of patients and associated costs escalates.

This study was aimed at determining the prevalence of depression among MDR-TB patients and reported a prevalence of 95.3% among patients.

Amreen and Rizvi N et al had done a study to determine the frequency of depression and anxiety among 100 (50 males and 50 females) tuberculosis patients with the help of Patient Health Questionnaire (PHQ-9) and Generalised Anxiety Disorder Questionnaire (GAD-7). They concluded that 56% TB patients had moderate-to-severe level of depression and 65% TB patients had moderate-to-severe level of anxiety. The percentage of moderate-to-severe depression in the present study are 45.38%.

Vega P et al had done a retrospective case series of the first 75 patients who have received individualised MDR-TB therapy in Lima, Peru. They have reported baseline prevalence of depression, anxiety and psychosis in 52.5%, 8.7% and 0% patients respectively. The present study showed higher percentage of depression in MDR-TB patients.

MA Sulhieri et al conducted a study to know the prevalence of depression among tuberculosis patients and Beck's Depression Inventory-II was used for data collection of all patients. They have found that 80% were suffering from depression and among whom 45.8% were moderately and 37.5% were severely depressed leading to long stay in hospital and high costs of medicine. Our results are also comparable to the present study. Mirza I et al reported the

prevalence of depression and anxiety in TB patients was about (47%). Mehreen S et al also had done a study to find out the frequency of depression at baseline (at the time of registration) in currently diagnosed MDR-TB patients and the emergence of depression during MDR-TB treatment in registered MDR-TB patients in PMDT. They had recruited 213 MDR-TB patients for the study. They stated that out of total patients, 139 (65.5%) had depression at baseline and at the end of 1st quarter only 47 (33.81%) out of 139 still had depression and at the end of 2nd quarter this number further decreased to 35 (15.10%) and while the emergence of depression was 36% at the end of both 1 and 2 quarter. Our results are also comparable to the present study. Javaid et al had done a study to know the depression and its associated factors with Multidrug-Resistant Tuberculosis at Baseline among 289 patients. They found that the percentage of mild depression, moderate depression and severe depression were 63.1%, 30.3% and 6.46% respectively. They also concluded that depression was not found in 88 (30.45%) patients. The percentage of severe depression in the present study are 25.38%. Baseline as well as ongoing monitoring of patient’s mental health status is very important as it may facilitate the health care professionals, patients and their family members in proper management of a patient’s condition during entire illness. Psychiatric co-morbidities are frequently associated with MDR-TB and their presence is not a contraindication to MDR-TB treatment.

CONCLUSION
In the present study, 95% of MDR tuberculosis patients were depressed at the time of registration. High rates of depression are likely related to long duration of treatment, social stigma, inadequate social support and the physiologic impact of chronic disease. The prevalence of depression was found to be more among males (86%) than the female TB patients having (71%) depression. Depression may also adversely affect the compliance to treatment and result in default, which in turn may have serious consequences of treatment failure and further extension in drug resistance. It is important to diagnose and treat depression in time to get the desired results of TB treatment.
